

SUMMER – 2023 EXAMINATION MODEL ANSWER

Subject: Advanced Computer Network

Subject Code: 22520

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

| <p>2.</p> | <p>Attempt any THREE of the following:</p> <p>(a) Describe flow control under SCTP.</p> <p>Ans. Flow control under SCTP Flow control in SCTP is similar to that in TCP. Like TCP, SCTP executes flow control to prevent overwhelming the receiver. In SCTP, we need to handle two units of data, the byte and the chunk. The values of rwnd and cwnd are expressed in bytes; the values of TSN and acknowledgments are expressed in chunks. Current SCTP implementations still use a byte-oriented window for flow control. Receiver Site: The receiver has one buffer (queue) and three variables. The queue holds the received data chunks that have not yet been read by the process. The first variable holds the last TSN received, cum TSN. The second variable holds the available buffer size; winSize. The third variable holds the last accumulative acknowledgment, last ACK. The following figure shows the queue and variables at the receiver site.</p>  <p>The diagram shows a 'Receiving queue' containing five data chunks with TSNs 26, 25, 24, 23, and 22. A 'winSize' bracket spans from the start of the queue to the end of chunk 26. An arrow labeled 'To process' points to the right from the end of the queue. Below the queue is a table of variables:</p> <table border="1" data-bbox="1016 1419 1242 1514"> <tr><td>26</td><td>cumTSN</td></tr> <tr><td>1000</td><td>winSize</td></tr> <tr><td>20</td><td>lastACK</td></tr> </table> <p>When the site receives a data chunk, it stores it at the end of the buffer (queue) and subtracts the size of the chunk from winSize. The TSN number of the chunk is stored in the cumTSN variable. 2. When the process reads a chunk, it removes it from the queue and adds the size of the removed chunk to winSize (recycling). 3. When the receiver decides to send a SACK, it checks the value of lastACK; if it is less than cumTSN, it sends a SACK with a cumulative TSN number equal to the cumTSN. It also includes the value of winSize as the advertised window size. Sender Site: The sender has one buffer (queue) and three variables: curTSN, rwnd, and inTransit, as</p> | 26 | cumTSN | 1000 | winSize | 20 | lastACK | <p>12 4M</p> <p><i>Diagram m 2M Explana tion 2M</i></p> |

MODEL ANSWER

Subject: Advanced Computer Network

Subject Code:

| |
|--------------|
| 22520 |
|--------------|

SUMMER – 2023 EXAMINATION MODEL ANSWER

The first variable, curTSN, refers to the next chunk to be sent. All chunks in the queue with a TSN less than this value have been sent, but not acknowledged; they are outstanding. The second variable, rwnd, holds the last value advertised by the receiver (in bytes). The third variable, inTransit, holds the number of bytes in transit, bytes sent but not yet acknowledged. The following is the procedure used by the sender.

1. A chunk pointed to by curTSN can be sent if the size of the data is less than or equal to the quantity $rwnd - inTransit$. After sending the chunk, the value of curTSN is incremented by 1 and now points to the next chunk to be sent. The value of inTransit is incremented by the size of the data in the transmitted chunk.
2. When a SACK is received, the chunks with a TSN less than or equal to the cumulative TSN in the SACK are removed from the queue and discarded. The sender does not have to worry about them anymore. The value of inTransit is reduced by the total size of the discarded chunks. The value of rwnd is updated with the value of the advertised window in the SACK.

SUMMER _ 2023 EXAMINATION

MODEL ANSWER

- The first field, ICMP type, defines the **type** of the message.
- The **code field** specifies the reason for the particular message type.
- The last common field is the **checksum field** for checking errors
- The rest of the header is specific for each message type.
- The data section in error messages carries information for finding the original packet that had the error. In query messages, the data section carries extra information based on the type of the
- Query.

| | | | |
|--|-----|-------------------------------------|----|
| | (c) | Describe SMTP with suitable diagram | 4M |
|--|-----|-------------------------------------|----|

SUMMER – 2023 EXAMINATION

MODEL ANSWER

Ans.

- It is an application layer protocol of TCP/IP model.
- It transfer messages from sender's mail servers to receivers mail server.
- SMTP interacts with local mail system and not user.
- SMTP uses a TCP socket on port 25 to transfer email reliably from client to server.
- Email is temporarily stored on the local and eventually transferred directly to receiving server.
- It is simple ASCII protocol.

on 2M*

COMMANDS & RESPONSE

SMTP uses commands and response to transfer message between

MTA client and MTA server

SUMMER – 2023 EXAMINATION MODEL ANSWER

SMTP Commands:

1. HELO: Used by client to identify itself.
2. MAIL FROM: Identify sender.
3. RCPT TO: Identify intended recipient.
4. DATA: Send actual message.
5. QUIT: Terminate the message.
6. RSET: Reset the connection
7. VRFY: Verify the add of recipient
8. HELP: Mail

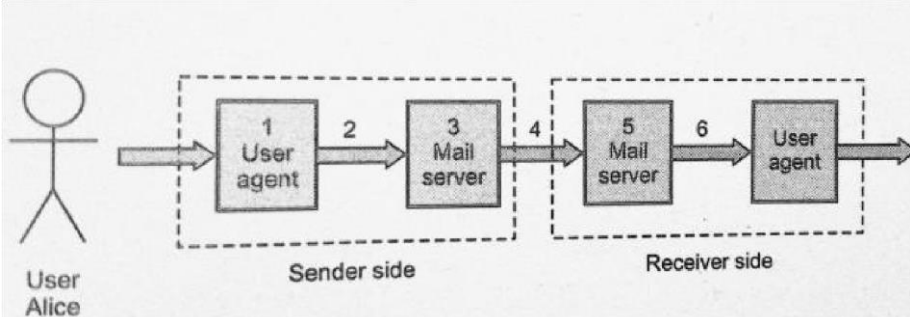

Example: Scenario: Alice sends message to Bob

1. Alice uses user agents (UA) to compose message and send to bob@technical.org.
2. Alice UA sends message to her mail server, message placed in

SUMMER – 2023 EXAMINATION

MODEL ANSWER

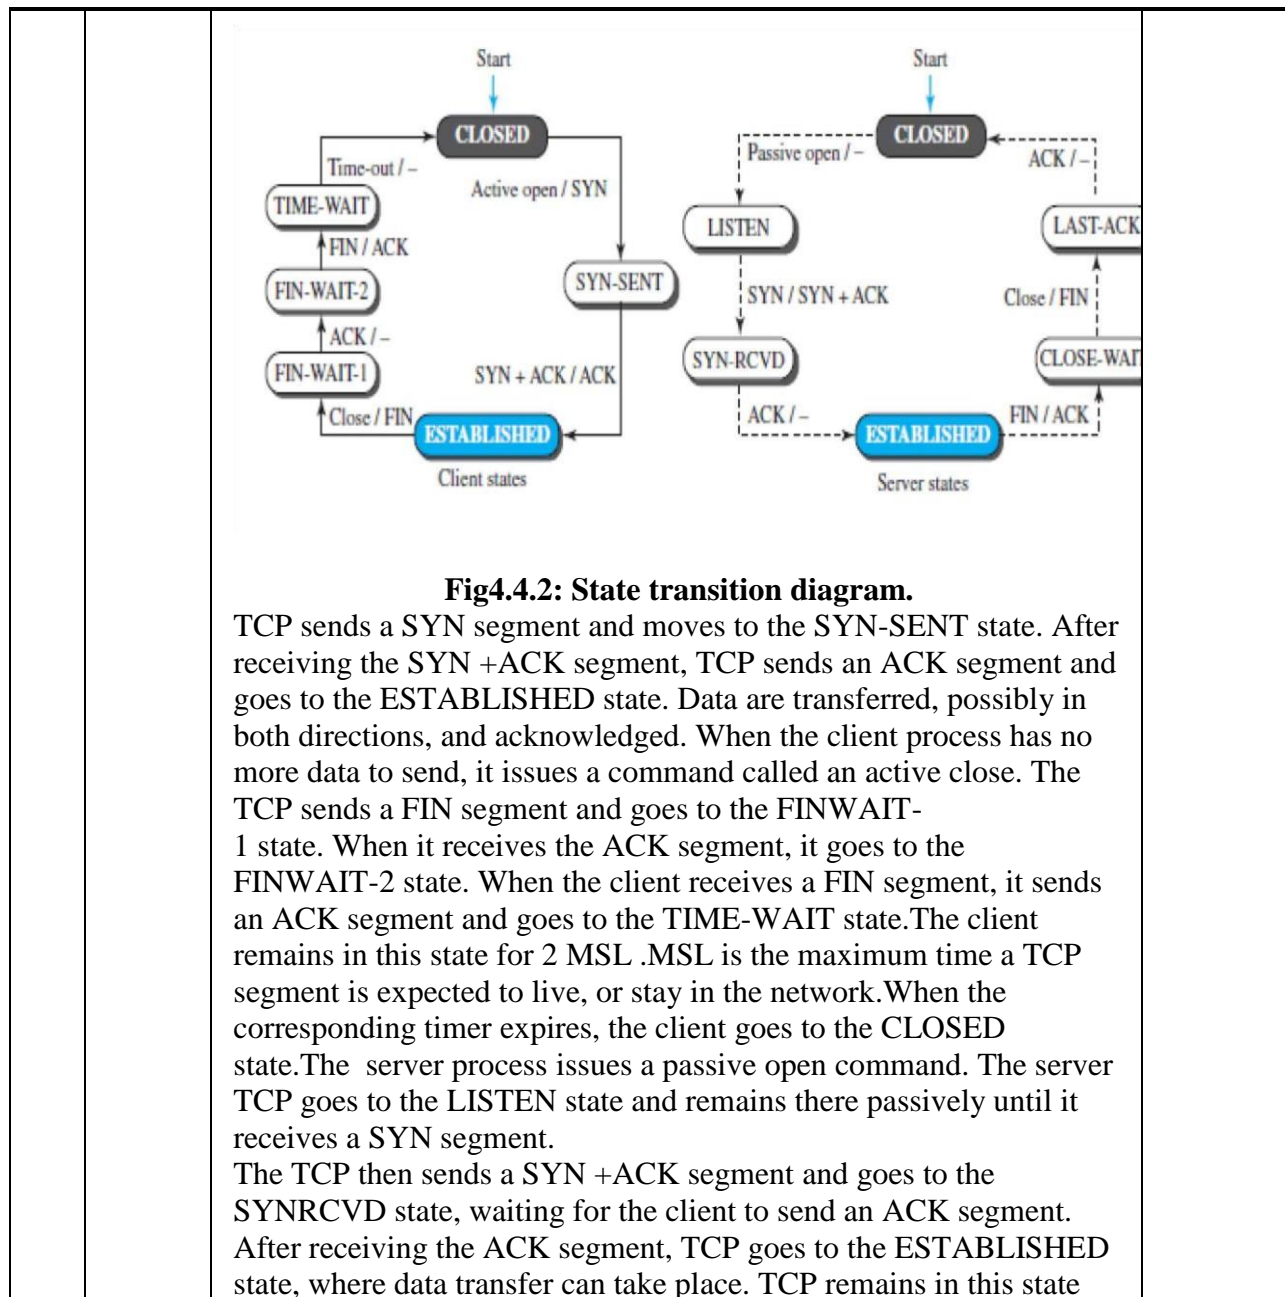

Fig4.4.2: State transition diagram.

TCP sends a SYN segment and moves to the SYN-SENT state. After receiving the SYN +ACK segment, TCP sends an ACK segment and goes to the ESTABLISHED state. Data are transferred, possibly in both directions, and acknowledged. When the client process has no more data to send, it issues a command called an active close. The TCP sends a FIN segment and goes to the FINWAIT-1 state. When it receives the ACK segment, it goes to the FINWAIT-2 state. When the client receives a FIN segment, it sends an ACK segment and goes to the TIME-WAIT state. The client remains in this state for 2 MSL .MSL is the maximum time a TCP segment is expected to live, or stay in the network. When the corresponding timer expires, the client goes to the CLOSED state. The server process issues a passive open command. The server TCP goes to the LISTEN state and remains there passively until it receives a SYN segment.

The TCP then sends a SYN +ACK segment and goes to the SYNRCVD state, waiting for the client to send an ACK segment. After receiving the ACK segment, TCP goes to the ESTABLISHED state, where data transfer can take place. TCP remains in this state

| | | <p>until it receives a FIN segment from the client signifying that there are no more data to be exchanged and the connection can be closed. The server, upon receiving the FIN segment, sends all queued data to the server with a virtual EOF marker, which means that the connection must be closed. It sends an ACK segment and goes to the CLOSEWAIT state, but postpones acknowledging the FIN segment received from the client until it receives a passive close command from its process. After receiving the passive close command, the server sends a FIN segment to the client and goes to the LASTACK state, waiting for the final ACK. When the ACK segment is received from the client, the server goes to the CLOSE state.</p> | |

| 5. | (a) | <p>Attempt any two of the following:</p> <p>Explain the process of transition form ipv4 to ipv6.</p> <p>Ans</p> <p>TRANSITION FROM IPV4 TO IPV6</p> <p>➤ There are 3 strategies have devised by IFTF to help transition. 1. Dual Stack 2. Tunnelling 3. Header Translation</p> <p>➤ Dual Stack:</p> <ol style="list-style-type: none"> 1. All the host must run IPV4 and IPV6 simultaneously until all the internet uses IPV6. 2. To determine which version to use when sending packet to destination, the source host queries the DNS. 3. If the DNS returns IPV4 address, the source host sends an IPV4 packet. If DNS returns an IPV6 address the source host sends an IPV6 packet. | <p>12M</p> <p>6M</p> <p><i>2M each for Correct process transition</i></p> |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|

➤ **Tunnelling:**

1. When two computers using IPV6 want to communicate with each other & the packet must pass through a region that uses IPV4.
2. The IPV6 packet is encapsulated in a IPV4 packet when it enter the region & leaves its capsule when it exits the region.

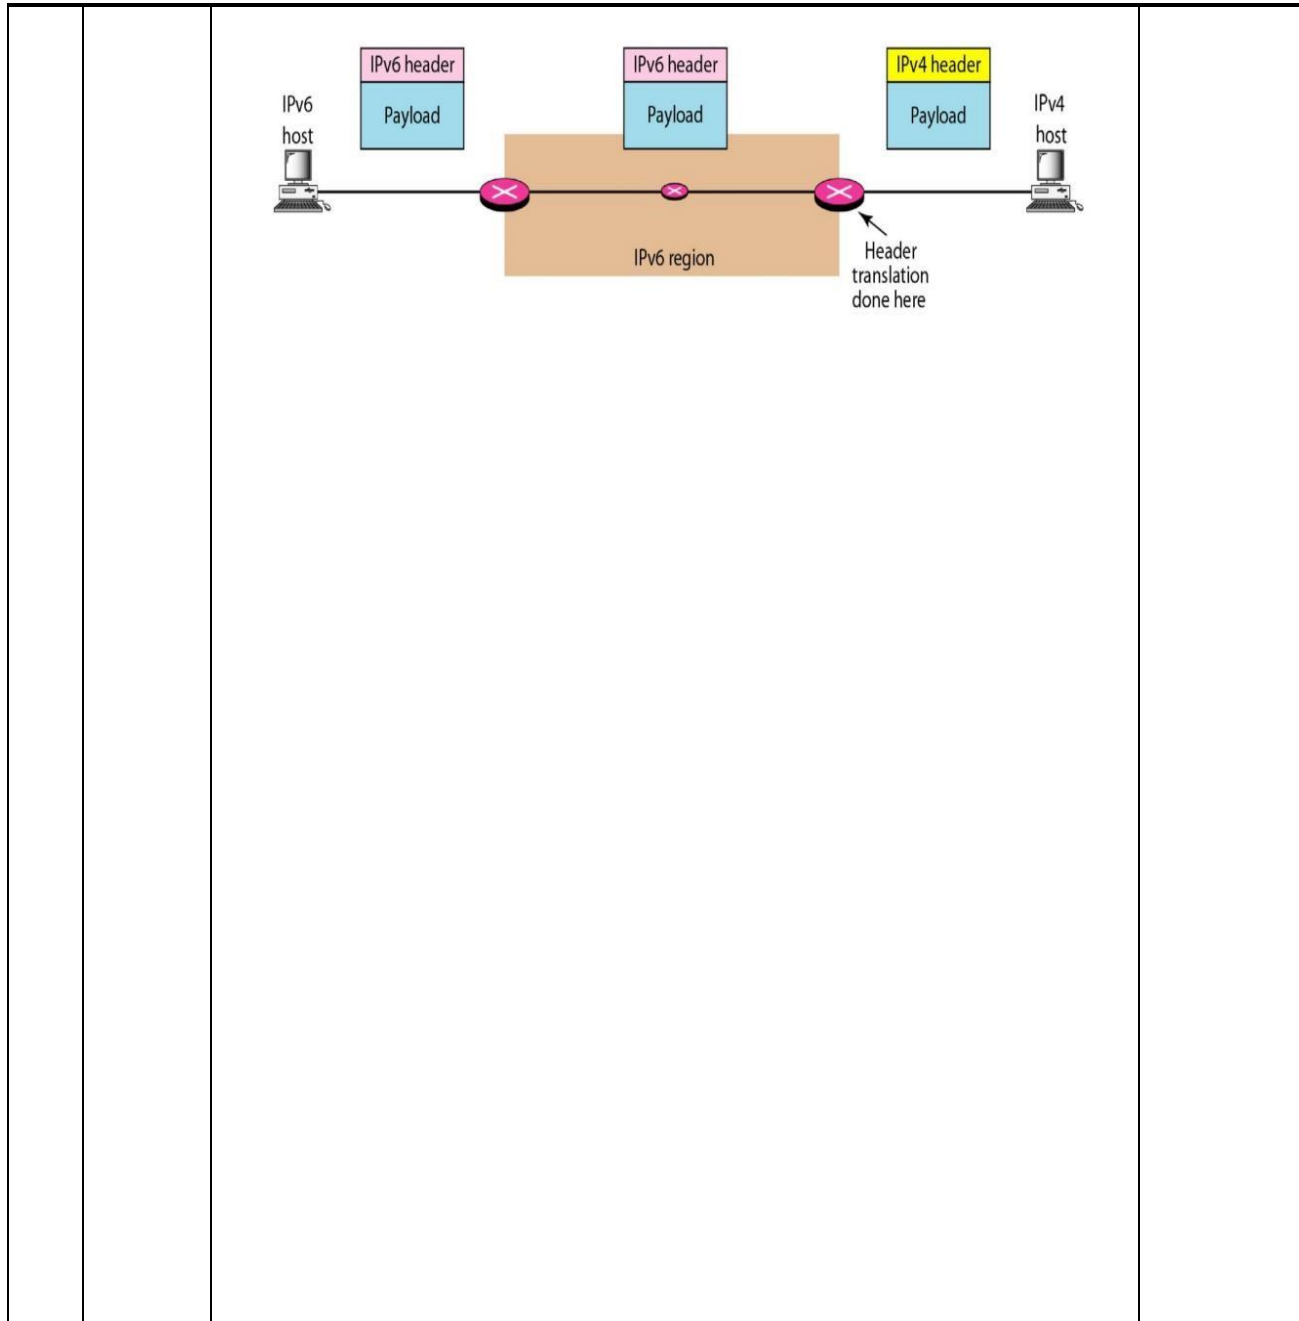

➤ **Header Translation:**

1. It is used when some of the system uses IPV4. the sender wants to use IPV6, but the receiver don't understand IPV6
2. The header format must be totally changed through header translation. The header of IPV6 packet is converted to IPV4 header.

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| <p>Ans.</p> | <p>TCP Flow Control is a protocol designed to manage the data flow between the user and the server. It ensures that there is a specific bandwidth for sending and receiving data so the data can be processed without facing any major issues. In order to achieve this, the TCP protocol uses a mechanism called the sliding window protocol.</p> <div style="text-align: center; margin: 20px 0;">  </div> <p>Error control in TCP is mainly done through the use of three simple techniques :</p> <ol style="list-style-type: none"> 1. Checksum – Every segment contains a checksum field which is used to find corrupted segments. If the segment is corrupted, then that segment is discarded by the destination TCP and is considered lost. 2. Acknowledgement – TCP has another mechanism called acknowledgement to affirm that the data segments have been delivered. Control segments that contain no data but have sequence numbers will be acknowledged as well but ACK segments are not acknowledged. 3. Retransmission – When a segment is missing, delayed to | <p><i>Each explanation of flow control 3M and error control 3M</i></p> |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|

| | <p>deliver to a receiver, corrupted when it is checked by the receiver then that segment is retransmitted again. Segments are retransmitted only during two events: when the sender receives three duplicate acknowledgements (ACK) or when a retransmission timer expires.</p> <ul style="list-style-type: none"> • Retransmission after RTO: TCP always preserves one retransmission time-out (RTO) timer for all sent but not acknowledged segments. When the timer runs out of time, the earliest segment is retransmitted. Here no timer is set for acknowledgement. In TCP, the RTO value is dynamic in nature and it is updated using the round trip time (RTT) of segments. RTT is the time duration needed for a segment to reach the receiver and an acknowledgement to be received by the sender. • Retransmission after Three duplicate ACK segments: RTO method works well when the value of RTO is small. If it is large, more time is needed to get confirmation about whether a segment has been delivered or not. Sometimes one segment is lost and the receiver receives so many out-of-order segments that they cannot be saved. In order to solve this situation, three duplicate acknowledgement method is used and missing segment is retransmitted immediately instead of retransmitting already delivered segment. This is a fast retransmission because it makes it possible to quickly retransmit lost segments instead of waiting for timer to end. | |

SUMMER – 2023 EXAMINATION MODEL ANSWER

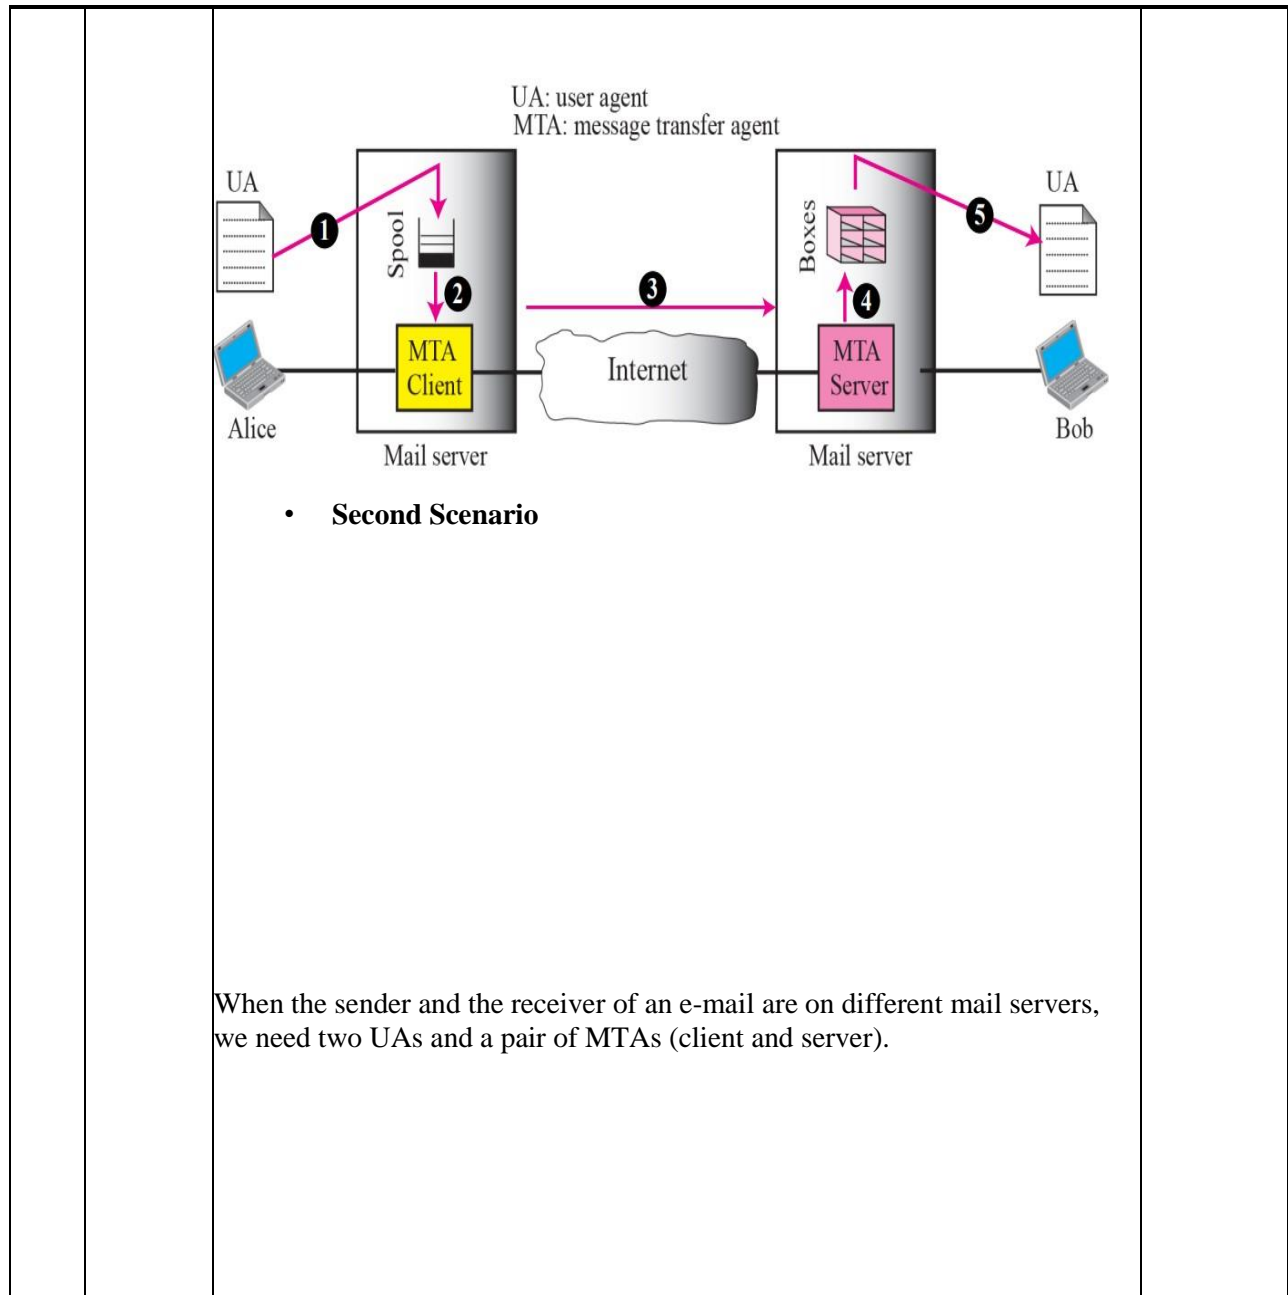

SUMMER – 2023 EXAMINATION

MODEL ANSWER

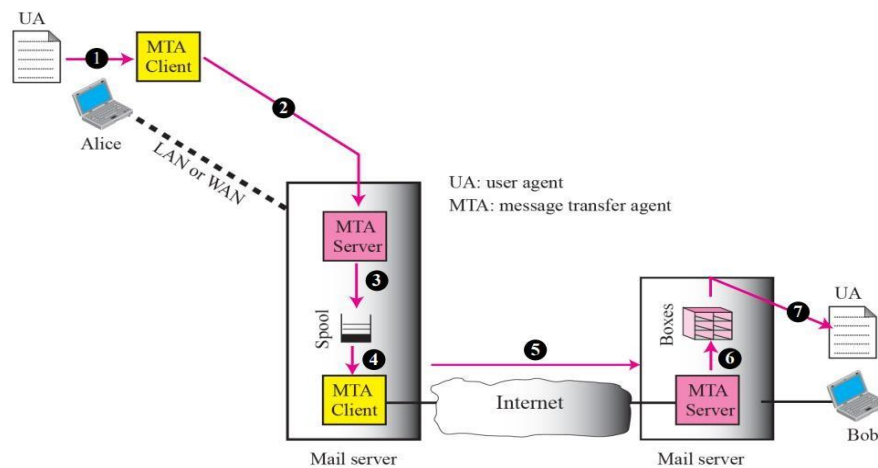

When the sender and the receiver of an e-mail are on the same mail server, we need only two user agents.

SUMMER _ 2023 EXAMINATION

MODEL ANSWER

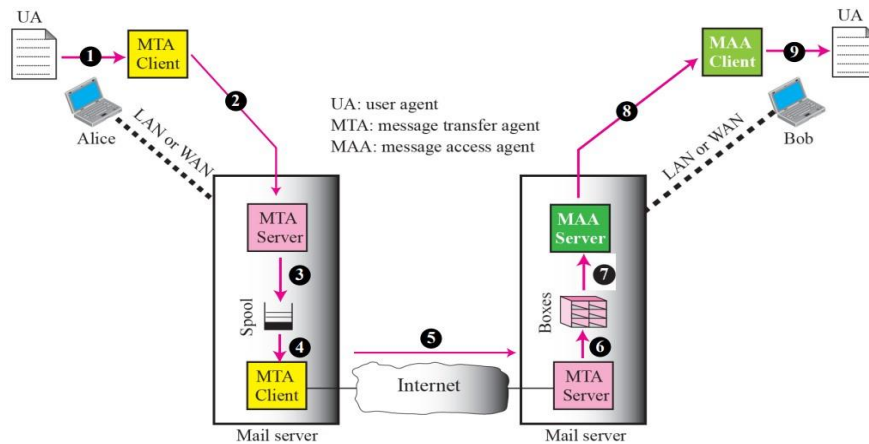

• **Third Scenario**

When the sender is connected to the mail server via a LAN or a WAN, we need two UAs and two pairs of MTAs (client and server).

• **Fourth Scenario**

When both sender and receiver are connected to the mail server via a LAN or a WAN, we need two UAs, two pairs of MTAs (client and server), and a pair of MAAs (client and server). This is the most common situation today.

| 6. | (a) Ans | <p>Attempt any TWO of the following: Explain Bellman Ford algorithm with suitable example</p> <p>i. Bellman ford algorithm is a single-source shortest path algorithm.</p> <p>ii. This algorithm is used to find the shortest distance from the single vertex to all the other vertices of a weighted graph.</p> <p>iii. Various other algorithms are used to find the shortest path, like the Dijkstra algorithm.</p> <p>iv. If the weighted graph contains the negative weight values, then the Dijkstra algorithm does not confirm whether it produces the correct answer or not.</p> <p>v. Rule for the algorithm: We will go on relaxing all the edges (n - 1) times where n = number of vertices</p> <p>vi. Relaxing means: If $(d(u) + c(u, v) < d(v))$ $d(v) = d(u) + c(u, v)$</p> | <p>12 6M</p> <p><i>3M for explanation and 3M for example</i></p> <p><i>Any other example shall be considered</i></p> |
|----|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|

vii. Consider the following example:-

Step 1: Let the given source vertex be 0. Initialize all distances as infinite, except the distance to the source itself. The total number of vertices in the graph is 5, so all edges must be processed 4 times.

| | A | B | C | D | E |
|---|---|---|---|---|---|
| 0 | ∞ | ∞ | ∞ | ∞ | ∞ |

Step 2: Let all edges are processed in the following order: (B, E), (D, B), (B, D), (A, B), (A, C), (D, C), (B, C), (E, D). We get the following distances when all edges are processed the first time. The first row shows initial distances. The second row shows distances when edges (B, E), (D, B), (B, D) and (A, B) are processed. The

SUMMER – 2023 EXAMINATION MODEL ANSWER

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | A | B | C | D | E |
|---|----------|----------|----------|----------|----------|
| 0 | ∞ | ∞ | ∞ | ∞ | ∞ |
| 0 | -1 | ∞ | ∞ | ∞ | ∞ |
| 0 | -1 | 4 | ∞ | ∞ | ∞ |
| 0 | -1 | 2 | ∞ | ∞ | ∞ |

Step 3: The first iteration guarantees to give all shortest paths which are at most 1 edge long. We get the following distances when all edges are processed second time (The last row shows final values).

| | A | B | C | D | E |
|---|----------|----------|----------|----------|----------|
| 0 | ∞ | ∞ | ∞ | ∞ | ∞ |
| 0 | -1 | ∞ | ∞ | ∞ | ∞ |
| 0 | -1 | 4 | ∞ | ∞ | ∞ |
| 0 | -1 | 2 | ∞ | ∞ | ∞ |
| 0 | -1 | 2 | ∞ | 1 | 1 |
| 0 | -1 | 2 | 1 | 1 | 1 |
| 0 | -1 | 2 | -2 | 1 | 1 |

Step 4: The second iteration guarantees to give all shortest paths which are at most 2 edges long. The algorithm processes all edges 2 more times. The distances are minimized after the second iteration, so third and fourth iterations do not update the distances.

| | <p>U(unordered bit), B(beginning bit), and E(ending bit). Usage of this field depends on the chunk type specified in the chunk type field.</p> <p>iii. Chunk Length: This field represents the size of the fields chunk type, chunk flag, chunk length, and chunk value, in bytes.</p> <p>5. SCTP DATA CHUNK: Data chunks are used to send actual data through the stream and have rather complex headers in some ways, but not really worse than TCP headers in general.</p> <p><u>SCTP Association Establishment Process:-</u> SCTP association startup and shutdown guidelines are described here. SCTP association is comprised of a four-way handshake that takes place in the following order:</p> <ol style="list-style-type: none"> i. The client sends an INIT signal to the server to initiate an association. ii. On receipt of the INIT signal, the server sends an INIT-ACK response to the client. This INIT-ACK signal contains a state cookie. This state cookie must contain a Message Authentication Code (MAC), along with a time stamp corresponding to the creation of the cookie, the life span of the state cookie, and the information necessary to establish the association. The MAC is computed by the server based on a secret key only known to it. iii. On receipt of this INIT-ACK signal, the client sends a COOKIE-ECHO response, which just echoes the state cookie. iv. After verifying the authenticity of the state cookie using the secret key, the server then allocates the resources for the association, sends a COOKIE-ACK response acknowledging the COOKIE-ECHO signal, and moves the association to ESTABLISHED state. | |

SUMMER _ 2023 EXAMINATION
MODEL ANSWER
WINTER – 2023 EXAMINATION Model
Answer – Only for the Use of RAC Assessors

Subject Name: Advanced Computer Network

Subject Code:

22520

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.
- 8) As per the policy decision of Maharashtra State Government, teaching in English/Marathi and Bilingual (English + Marathi) medium is introduced at first year of AICTE diploma Programme from academic year 2021-2022. Hence if the students write answers in Marathi or bilingual language (English +Marathi), the Examiner shall consider the same and assess the answer based on matching of concepts with model answer.

| | | |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| | <p>Ans The need of IPv6 are as follows:</p> <ol style="list-style-type: none"> Address Space: IPv6 provides a significantly larger address space compared to IPv4, allowing for the accommodation of the growing number of devices connected to the internet. Addressing Efficiency: IPv6 simplifies address assignment and management, eliminating the need for Network Address Translation (NAT) and making subnetting more efficient. Auto-Configuration: IPv6 supports stateless address auto-configuration, enabling devices to automatically configure their IPv6 addresses without the need for DHCP (Dynamic Host Configuration Protocol). Security Improvements: IPv6 includes features like IPsec (Internet Protocol Security) as a standard, enhancing the security of communications between devices. Multicast and Any cast: IPv6 incorporates improved support for multicast communication, enabling efficient one-to-many communication. Anycast is also more easily implemented in IPv6. Mobility Support: IPv6 is designed to better support mobile devices, ensuring seamless connectivity as devices move between networks. Simplified Header Structure: IPv6 has a simpler and more efficient header structure, reducing processing overhead on networking devices. Future-Proofing: As the successor to IPv4, IPv6 is essential for the continued growth of the internet and the proliferation of connected devices, ensuring there are enough unique addresses for future expansion. | <p>Any 2 correct need 1M each</p> |
| | <p>c Elaborate need of domain name system.</p> | <p>2 M</p> |
| | <p>Ans</p> <ol style="list-style-type: none"> DNS ensures the internet is not only user-friendly but also works smoothly, loading whatever content we ask for quickly and efficiently. It allows the user to access remote system by entering human readable device hostnames instead of IP address. It translates domain name into IP addresses so browser can load internet resources. It translates human readable domain names into the numerical identifiers associated with networking equipment, enabling devices to be located and connected worldwide. <p>Analogous to a network “phone book,” DNS is how a browser can translate a domain name (e.g., “facebook.com”) to the actual IP address of the server, which stores the information requested by the browser.</p> | <p>Correct explanati on 2M</p> |
| | <p>d List any 2 features of TCP.</p> | <p>2 M</p> |

**SUMMER _ 2023 EXAMINATION
MODEL ANSWER**

| | | | | | | | |
|------------|---------|---------------------|---------------------------------------------|----------------------|------------|-------|--|
| Ans | 4-11 | 12-31 | 2M Explanati on & 2M Diagram | | | | |
| | 0-3 | Version | | Traffic Class | Flow Label | | |
| | 32-47 | Payload Length | | 48-55 Next Header | Hop Limit | 56-63 | |
| | 64-191 | Source Address | | | | | |
| | 192-288 | Destination Address | | | | | |

Version (4-bits): It represents the version of Internet Protocol, i.e. 0110.

Traffic Class (8-bits): These 8 bits are divided into two parts. The most significant 6 bits are used for Type of Service to let the Router Known what services should be provided to this packet.

Flow Label (20-bits): This label is used to maintain the sequential flow of the packets belonging to a communication. The source labels the sequence to help the router identify that a particular packet belongs to a specific flow of information. This field helps avoid re-ordering of data packets. It is designed for streaming/real-time media.

Payload Length (16-bits): This field is used to tell the routers how much information a particular packet contains in its payload. Payload is composed of Extension Headers and Upper Layer data.

Next Header (8-bits): This field is used to indicate either the type of Extension Header, or if the Extension Header is not present then it indicates the Upper Layer PDU. The values for the type of Upper Layer PDU are same as IPv4's.

Hop Limit (8-bits): This field is used to stop packet to loop in the network infinitely. This is same as TTL in IPv4. The value of Hop Limit field is decremented by 1 as it passes a link. When the field reaches 0 the packet is discarded.

Source Address (128-bits): This field indicates the address of originator of the packet.

SUMMER – 2023 EXAMINATION MODEL ANSWER

| | | |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| | <p>Destination Address (128-bits): This field provides the address of intended recipient of the packet.</p> <p>Extension Headers When Extension Headers are used, IPv6 Fixed Header's Next Header field points to the first Extension Header. If there is one more Extension Header, then the first Extension Header's 'Next-Header' field points to the second one, and so on. The last Extension Header's 'Next-Header' field points to the Upper Layer Header. Thus, all the headers points to the next one in a linked list manner.</p> | |
| b | Explain Bellman Ford algorithm with suitable example. | 4 M |

**SUMMER _ 2023 EXAMINATION
MODEL ANSWER**

| | | |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| <p>Ans</p> | <p>Dynamic Programming is used in the Bellman-Ford algorithm. It begins with a starting vertex and calculates the distances between other vertices that a single edge can reach. It then searches for a path with two edges, and so on. The Bellman-Ford algorithm uses the bottom-up approach.</p> <p><u>Bellman Ford's algorithm</u></p> <p>The Bellman-Ford algorithm works by grossly underestimating the length of the path from the starting vertex to all other vertices.</p> <p>Step 1: Make a list of all the graph's edges. This is simple if an adjacency list represents the graph.</p> <p>Step 2: "V - 1" is used to calculate the number of iterations. Because the shortest distance to an edge can be adjusted V - 1 time at most, the number of iterations will increase the same number of vertices.</p> <p>Step 3: Begin with an arbitrary vertex and a minimum distance of zero. Because you are exaggerating the actual distances, all other nodes should be assigned infinity.</p> <p>For each edge u-v, relax the path lengths for the vertices: If</p> <p>distance[v] is greater than distance[u] + edge weight uv, then</p> <p>distance[v] = distance[u] + edge weight uv</p> <p>Step 4: If the new distance is less than the previous one, update the distance for each Edge in each iteration. The distance to each node is the total distance from the starting node to this specific node.</p> <p>Step 5: To ensure that all possible paths are considered, you must consider alliterations. You will end up with the shortest distance if you do this.</p> | <p>2M Algorith m, 2M Example</p> |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|

Step 1: Start with the weighted graph

Step 2: Choose a starting vertex and assign infinity path values to all other vertices

Step 3: Visit each edge and relax the path distances if they are inaccurate

SUMMER _ 2023 EXAMINATION
MODEL ANSWER

Step 4: We need to do this V times because in the worst case, a vertex's path length might need to be readjusted V times

Step 5: Notice how the vertex at the top right corner had its path length adjusted

Step 6: After all the vertices have their path lengths, we check if a negative cycle is present

It acts as an interface between the user and the World Wide Web by displaying web pages Web browsers communicate with web servers using the HTTP or HTTPS protocol, which allows users to access websites hosted on remote servers. 3. A web server is a computer program that serves web pages to clients, such as web browsers, upon request. It is responsible for hosting websites, processing HTTP requests, and delivering web content to users online. 4. Hyperlinks one of the key features of the Web is hyperlinks, which allow you to navigate between web pages by clicking on links. 5. Uniform Resource Locators (URLs) Web pages are identified by URLs, which are unique addresses that point to the location of the web page on the Internet. | |

|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <p>Ans</p> | <p>Electronic Mail (e-mail) is one of the most widely used services of the Internet. This service allows an Internet user to send a message in a formatted manner (mail) to other Internet users in any part of the world. Message in the mail not only contain text, but it also contains images, audio and videos data. The person who is sending mail is called sender and person who receives mail is called the recipient. Format of E-mail: An e-mail consists of three parts that are as follows:</p> <ol style="list-style-type: none"> 1. Envelope 2. Header 3. Body <div style="text-align: center;">  </div> <p>Header: The header consists of a series of lines. Each header field consists of a single line of ASCII text specifying field name, colon and value. The main header fields related to message transport are:</p> <ol style="list-style-type: none"> 1. To: It specifies the DNS address of the primary recipient(s). 2. Cc: It refers to carbon copy. It specifies address of secondary recipient(s). 3. BCC: It refers to blind carbon copy. It is very similar to Cc. The only difference between Cc and Bcc is that it allows user to send copy to the third party without primary and secondary recipient knowing about this. 4. From: It specifies name of person who wrote message. | <p>2M Descripti on & 2M for Message format diagram</p> |

**SUMMER _ 2023 EXAMINATION
MODEL ANSWER**

| | | | | | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|-------------|
| e | Compare POP3 with IMAD on below Points. i) TCP Port used ii) E-mail Stored at iii) Time required to connect iv) Multiple mail boxes. | | | 4 M | |
| Ans | Under the term IMAD as an IMAP | | | Each correct Point 1 M Note: Consider the term IMAD as an IMAP | |
| | Points | POP3 | | | IMAP |
| | TCP Port used | Uses port 110 (unencrypted) or port 995 (encrypted/SSL) | Uses port 143 (unencrypted) or port 993 (encrypted/SSL) | | |
| | E-mail Stored at | Emails are typically downloaded from the server to the client device. The emails are then stored locally on the device, and the server copy is usually deleted. | Emails are stored on the mail server. The client accesses and manages emails directly on the server, allowing for synchronization across multiple devices. | | |
| 5 | Time required to connect | Generally faster to connect because it involves downloading emails to the client device. Connection time is minimal since it retrieves emails and disconnects from the server. | May take more time to connect as it involves syncing with the server and fetching email headers. However, subsequent access to emails is faster as only headers are initially downloaded. | | |
| | Multiple mail boxes. | Usually does not support multiple mailboxes. Emails are typically downloaded to a single device, and managing emails on multiple devices can be challenging. | Supports multiple mailboxes and folders Changes made on one device (e.g., marking an email as read) are reflected on all devices since the emails are stored centrally on the server. | | |
| 5 | Attempt any TWO of the following: | | | 12 M | |
| a | Explain how TCP connections are established using 3 way handshake. | | | 6 M | |

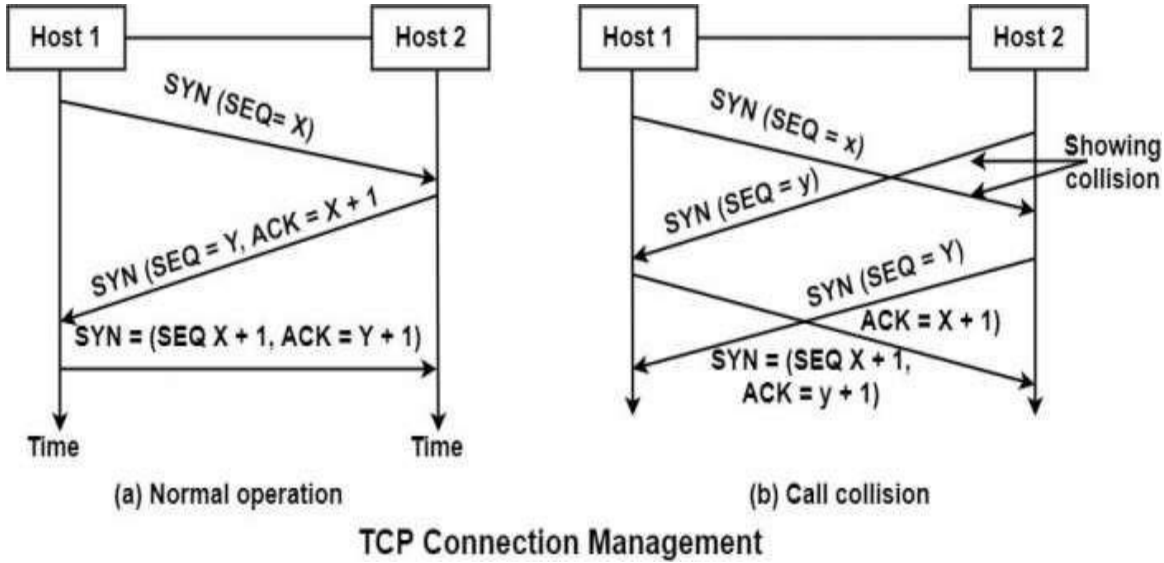

| | | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| <p>Ans</p> | <p>TCP Connection: When you establish a new TCP connection (3-way handshake) then the initial sequence number is a random 32-bit value. The receiver will use this sequence number and send back an acknowledgment. Protocol analyzers like Wireshark will often use a relative sequence number of 0 since it's easier to read than some high random number.</p> <p>TCP uses a three-way handshake to establish a reliable connection. The connection is full duplex, and both sides synchronize (SYN) and acknowledge (ACK) each other. The exchange of these four flags is performed in three steps: SYN, SYN-ACK, ACK, as shown in figure below</p>  <p>The client chooses an initial sequence number, set in the first SYN packet. The server also chooses its own initial sequence number, set in the SYN/ACK packet. Each side acknowledges each other's sequence number by incrementing it: this is the acknowledgement number. The use of sequence and acknowledgement numbers allows both sides to detect missing or out-of-order segments.</p> <p>Once a connection is established, ACKs typically follow for each segment. The connection will eventually end with a RST (reset or tear down the connection) or FIN (gracefully end the connection).</p> <p>Three-Way Handshake: The algorithm used by TCP to establish and terminate a connection is called a three-way handshake. We first describe the basic algorithm and then show how it is used by TCP.</p> | <p>2M for diagram, 1 M for TCP Connection and 3M for 3-way handshake explanation</p> |

MODEL ANSWER**

| | | |
|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| | <p>The three-way handshake involves the exchange of three messages between the client and the server, as we see in below figure</p>  | |
| b | Demonstrate with suitable example of call collision in TCP connection. | 6 M |

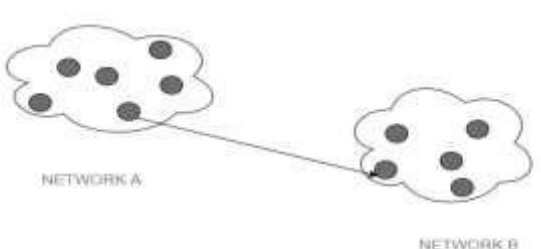

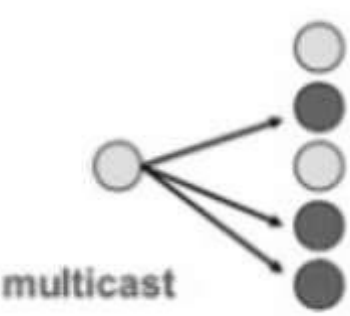

| | | |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <p>Ans</p> | <p>The connection is established in TCP using the three-way handshake as discussed earlier to create a connection. One side, say the server, passively stays for an incoming link by implementing the LISTEN and ACCEPT primitives, either determining a particular other side or nobody in particular. The other side performs a connect primitive specifying the I/O port to which it wants to join. The maximum TCP segment size available, other options are optionally like some private data (example password). The CONNECT primitive transmits a TCP segment with the SYN bit on and the ACK bit off and waits for a response. The sequence of TCP segments sent in the typical case, as shown in the figure below –</p>  <p style="text-align: center;">TCP Connection Management</p> <p>When the segment sent by Host-1 reaches the destination, i.e., host -2, the receiving server checks to see if there is a process that has done a LISTEN on the port given in the destination port field. If not, it sends a response with the RST bit on to refuse the connection. Otherwise, it governs the TCP segment to the listing process, which can accept or decline (for example, if it does not look similar to the client) the connection.</p> <p>Call Collision: If two hosts try to establish a connection simultaneously between the same two sockets, then the events sequence is demonstrated in the figure under such circumstances. Only one connection is established. It cannot select both the links because their endpoints identify connections.</p> | <p>1 M for diagram, 2 M for TCP connectio n And 3M for call collision</p> |

**SUMMER _ 2023 EXAMINATION
MODEL ANSWER**

| | | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| | <p>Suppose the first set up results in a connection identified by (x, y) and the second connection are also released up. In that case, only tail enter will be made, i.e., for (x, y) for the initial sequence number, a clock-based scheme is used, with a clock pulse coming after every 4 microseconds. For ensuring additional safety when a host crashes, it may not reboot for sec, which is the maximum packet lifetime. This is to make sure that no packets from previous connections are roaming around.</p> | |
| c | <p>Explain following address types of IPv6:</p> <ul style="list-style-type: none"> a) Unicast address b) Multicast address c) Anycast address | 6 M |

| | | |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| <p>Ans</p> | <p>The three types of IPv6 addresses are: unicast, anycast, and multicast.</p> <p>a) Unicast address: This type of information transfer is useful when there is a participation of single sender and single recipient. So, in short you can term it as a one-to-one transmission. For example, a device having IP address 10.1.2.0 in a network wants to send the traffic stream (data packets) to the device with IP address 20.12.4.2 in the other network, then unicast comes into picture. This is the most common form of data transfer over the networks.</p>  <p style="text-align: center;">UNICAST EXAMPLE</p> <p>b) Multicast address: In multicasting, one/more senders and one/more recipients participate in data transfer traffic. In this method traffic recline between the boundaries of unicast (one-to-one) and broadcast (one-to-all). Multicast lets server's direct single copies of data streams that are then simulated and routed to hosts that request it. IP multicast requires support of some other protocols like IGMP (Internet Group Management Protocol), Multicast routing for its working. Also, in Classful IP addressing Class D is reserved for multicast groups.</p>  <p>c) Anycast address: An IPv6 anycast address is an address that is assigned to more than one interface (typically belonging to different nodes), where a packet sent to an anycast address is routed to the nearest interface having that address, according to the</p> | <p>2 M for each address types</p> |

SUMMER – 2023 EXAMINATION MODEL ANSWER

| | | | |
|----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| | | wants to carry its traffic. This capability is sometimes called source selected policies. You implement this by configuring anycast addresses to identify the set of routers belonging to Internet service providers (for example, one anycast address per Internet service provider). You can use these anycast addresses as intermediate addresses in an IPv6 routing header, to cause a packet to be delivered by a particular provider or sequence of providers. You can also use anycast addresses to identify the set of routers attached to a particular subnet or the set of routers providing entry into a particular routing domain. You can locate anycast addresses from the unicast address space by using any of the defined unicast address formats. Thus, anycast addresses are syntactically indistinguishable from unicast addresses. When you assign a unicast address to more than one interface, that is, turning it into an anycast address, you must explicitly configure the nodes to which the address is assigned in order to know that it is an anycast address. | |

MODEL ANSWER**

| | | |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| <p>Ans</p> | <p>1. Distance Vector Routing Protocol: A distance-vector routing protocol in data networks determines the best route for data packets based on distance. Distance-vector routing protocols measure the distance by the number of routers a packet has to pass, one router counts as one hop. Some distance-vector protocols also take into account network latency and other factors that influence traffic on a given route. To determine the best route across a network, routers, on which a distance-vector protocol is implemented, exchange information with one another, usually routing tables plus hop counts for destination networks and possibly other traffic information. Distance-vector routing protocols also require that a router informs its neighbours of network topology changes periodically.</p> <p>Distance Vector Algorithm –</p> <ul style="list-style-type: none"> • A router transmits its distance vector to each of its neighbours in a routing packet. • Each router receives and saves the most recently received distance vector from each of its neighbours. • A router recalculates its distance vector when: • It receives a distance vector from a neighbour containing different information than before. • It discovers that a link to a neighbour has gone down. <p>2. Open Shortest Path First (OSPF) Protocol:</p> <p>The OSPF (Open Shortest Path First) protocol is one of a family of IP Routing protocols, and is an Interior Gateway Protocol (IGP) for the Internet, used to distribute IP routing information throughout a single Autonomous System (AS) in an IP network. The OSPF protocol is a link-state routing protocol, which means that the routers exchange topology information with their nearest neighbours. The topology information is flooded throughout the AS, so that every router within the AS has a complete picture of the topology of the AS. This picture is then used to calculate end-to-end paths through the AS, normally using a variant of the Dijkstra algorithm. Therefore, in a link-state routing protocol, the next hop address to which data is forwarded is determined by choosing the best end-to-end path to the eventual destination.</p> | <p>3 M for each Protocol</p> |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|

SUMMER – 2023 EXAMINATION MODEL ANSWER

| | | |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| | <p>Each OSPF router distributes information about its local state (usable interfaces and reachable neighbors, and the cost of using each interface) to other routers using a Link State Advertisement (LSA) message. Each router uses the received messages to build up an identical database that describes the topology of the AS.</p> <p>From this database, each router calculates its own routing table using a Shortest Path First (SPF) or Dijkstra algorithm. This routing table contains all the destinations the routing protocol knows about, associated with a next hop IP address and outgoing interface. The protocol recalculates routes when network topology changes, using the Dijkstra algorithm, and minimizes the routing protocol traffic that it generates.</p> <p>It provides support for multiple paths of equal cost.</p> <p>It provides a multi-level hierarchy (two-level for OSPF) called "area routing," so that information about the topology within a defined area of the AS is hidden from routers outside this area. This enables an additional level of routing protection and a reduction in routing protocol traffic.</p> <p>All protocol exchanges can be authenticated so that only trusted routers can join in the routing exchanges for the AS.</p> | |
| <p>b</p> | <p>For the IP address given below:</p> <ol style="list-style-type: none"> 1) Identify the classes to which IP address belongs to 2) Identify Network address section 3) Identify Host address section 4) Calculate number of hosts can be assigned with each network <p>i)122.34.45.133 ii)12.12.12.12 iii)192.10.233.26</p> | <p>6 M</p> |

| c | Describe DHCP operations, when DHCP client and server on same network. | 6 M |

Ans

DHCP is based on a client-server model and based on discovery, offer, request, and ACK. DHCP client and server can either be on the same network or on different networks. DHCP (Dynamic Host Configuration Protocol) is a network management protocol used to dynamically assign an IP address to any device, or node, on a network so it can communicate using IP. DHCP automates and centrally manages these configurations rather than requiring network administrators to manually assign IP addresses to all network devices. DHCP can be implemented on small local networks, as well as large enterprise networks. DHCP assigns new IP addresses in each location when devices are moved from place to place, which means network administrators do not have to manually configure each device with a valid IP address or reconfigure the device with a new IP address if it moves to a new location on the network.

2 M for diagram and 4 M for Explanation

In this case, the operation can be described as follows:

1. The DHCP server issues a passive open command on UDP port number 67 and waits for a client.
2. A booted client issues an active open command on port number 68. The message is encapsulated in a UDP user datagram, using the destination port number 67 and the source port number 68.
3. The server responds with either a broadcast or a unicast message using UDP source port number 67 and destination port number 68.

MODEL ANSWER

COMMANDS & RESPONSE

SMTP uses commands and response to transfer message between MTA client and MTA server

SMTP Commands:

1. HELO: Used by client to identify itself.
2. MAIL FROM: Identify sender.
3. RCPT TO: Identify intended recipient.
4. DATA: Send actual message.
5. QUIT: Terminate the message.
6. RSET: Reset the connection.
7. VRFY: Verify the add of recipient
8. HELP: Mail

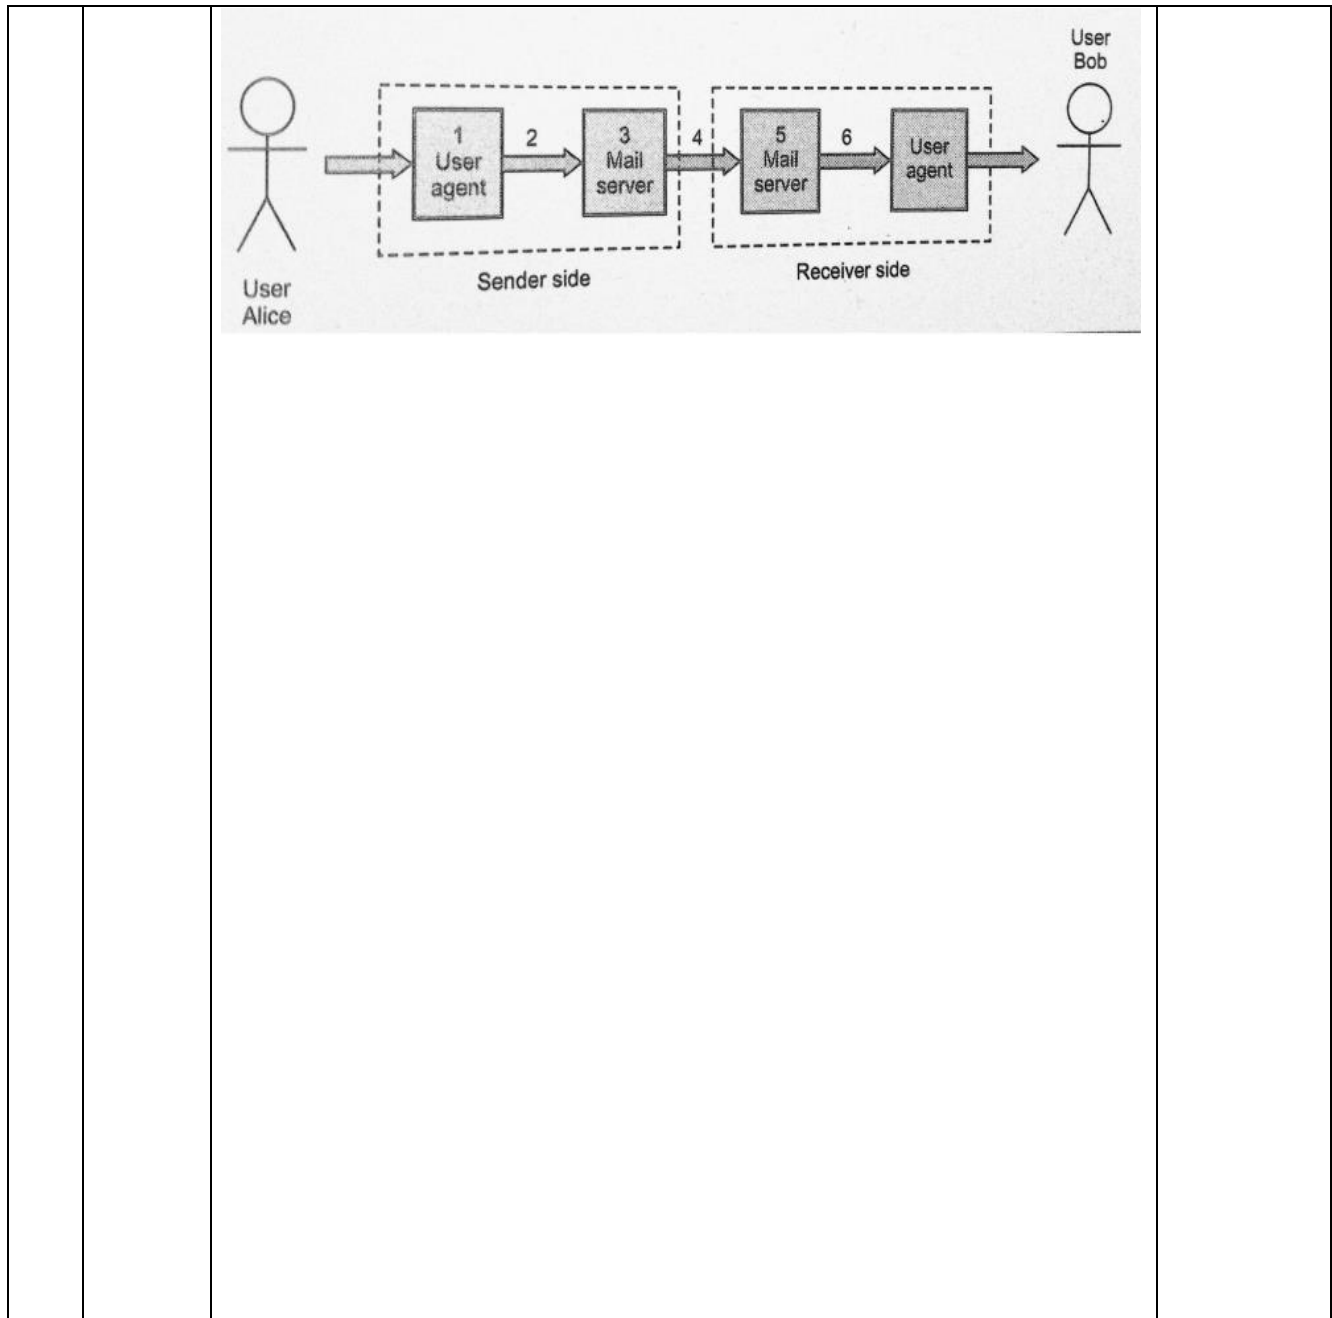

Example: Scenario: Alice sends message to Bob

1. Alice uses user agents (UA) to compose message and send to bob@technical.org.
2. Alice UA sends message to her mail server, message placed in message queue.
3. Client side of SMTP opens TCP connection with Bob's mail server.
4. SMTP client sends Alice message over TCP connection. 5. Bob's mail server places the message in Bob's mailbox.
6. Bob invokes his user agent to read message.

| | <p>e)</p> <p>Ans</p> | <p>Construct a diagram to show the application of cookies in a scenario in which the server uses cookies for advertisement.</p> <p>Cookies are small files which are stored on a user’s computer. They are used to hold a modest amount of data specific to a particular client and website and can be accessed either by the web server or by the client computer.</p>  <pre> graph LR Browser[Browser] -- "1) Request" --> Server[Server] Server -- "2) Response + Cookie" --> Browser Browser -- "3) Request + Cookie" --> Server </pre> <p>When cookies were invented, they were basically little documents containing information about you and your preferences. For instance, when you select your language in which you want to view your website, the website would save the information in a document called a cookie on your computer, and the next time when you visit the website, it would be able to read a cookie saved earlier.</p> <p>That way the website could remember your language and let you view the website in your preferred language without having to select the language again.</p> <p>A cookie can contain any type of information such as the time when you visited the website, the items that you added into your shopping basket, all the links you clicked in website, etc. Cookies themselves contain no personally identifiable information. Depending on the publisher’s and the user’s settings, information associated with cookies used in advertising may be added to the user’s Google Account.</p> | <p>4M</p> <p><i>2M for Explanation & 2M for Diagram</i></p> |
|--|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|

Most commonly, AdSense sends a cookie to the browser when a user visits a page that shows Google ads. Pages with Google ads include ad tags that instruct browsers to request ad content from our servers. When the server delivers the ad content, it also sends a cookie. But a page doesn't have to show Google ads for this to happen; it just needs to include our ad tags, which might load a click tracker or impression pixel instead. Following Fig. Example of how server uses cookies for advertisement.

| | <p>b) Ans</p> | <p>Describe DHCP with its operation & static dynamic allocation. The Domain Name System, more popular as DNS, and the Dynamic Host Configuration Protocol, also known as DHCP, represent two crucial TCP/IP areas of a Windows NT Server network. The DNS is responsible for converting hostnames into IP addresses, while the DHCP is engaged in assigning unique dynamic IP addresses and the corresponding subnet masks and default gateways to TCP/IP running computers within a particular server network. Thanks to the dynamic addressing executed by the DHCP, a computer can have a different IP address every time it connects to the network it belongs to, without the intervention of a UNIX administrator. Through this DHCP functionality every new computer added to a network is automatically assigned a unique IP address.</p> | |

| | | <p>DHCP servers greatly simplify the configuration of networks and are built in the majority of the wireless access points and wired Ethernet routers. In a network, a DHCP server manages a pool of IP addresses, as well as default gateway details, DNS details and other information for the clients' network configuration. When a new computer is introduced into a DHCP server-enabled network, it will send a query to the DHCP server requesting all the necessary information. When the query reaches the DHCP server, it will grant the new computer a new IP address and a lease - a time frame for which the computer can use this IP address, as well as other configuration details. The whole process takes place immediately after the new computer boots, and to be successful, it has to be completed before initiating IP based communication with other hosts in the network.</p> <p>STATIC ALLOCATION The static allocation method is very popular in modern ISP networks, which do not use dial-up methods. With the static allocation, the DHCP sever keeps a database with all clients' LAN MAC addresses and gives them an IP address only if their MAC address is in the database. This way, the clients can be sure that they will be getting the same IP address every time.</p> <p>DYNAMIC ALLOCATION When the DHCP server is configured to use dynamic allocation, this means that it uses a lease policy. This way, when an assigned IP address from the available pool is no longer used, it will be transferred back to the pool, making it available for someone else to use. The advantage of this method is that the IP addresses are used to their maximum - as soon as they are no longer used by the client, they are instantly made available to others. The disadvantage of this method is that a client will always have a random IP address.</p> | |

| | <p>c) Ans</p> | <p>Describe Email security Over non-secure channel.</p> <ul style="list-style-type: none"> • Email security describes different techniques for keeping sensitive information in email communication and accounts secure against unauthorized access, loss or compromise • Email is often used to spread malware, spam and phishing attacks. Attackers use deceptive messages to entice recipients to part with sensitive information, open attachments or click on hyperlinks that install malware on the victim's device. • Email encryption involves encrypting, or disguising, the content of email messages to protect potentially sensitive information from being read by anyone other than intended recipients. Email encryption often includes authentication. • Email allows attackers to use it as a way to cause problems in attempt to profit. Whether through spam campaigns, malware and phishing attacks, sophisticated targeted attacks, or business email compromise (BEC), attackers try to take advantage of the lack of security of email to carry out their actions. | <p>6M</p> <p><i>Any 6 points 1M each</i></p> |

SUMMER – 2023 EXAMINATION MODEL ANSWER

| | | | |
|--|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | | <ul style="list-style-type: none"> • Since most organizations rely on email to do business, attackers exploit email in an attempt to steal sensitive information. • Because email is an open format, it can be viewed by anyone who can intercept it. It can be easily read and the contents of an email by intercepting it. • Email Security Policies can be established by viewing the contents of emails flowing through their email servers. It's important to understand what is in the entire email in order to act appropriately. After these baseline policies are put into effect, an organization can enact various security policies on those emails. • These email security policies can be as simple as removing all executable content from emails to more in-depth actions, like sending suspicious content to a sandboxing tool for detailed analysis. • If security incidents are detected by these policies, the organization needs to have actionable intelligence about the scope of the attack. • Enforce email encryption policies to prevent sensitive email information from falling into the wrong hands. • An email gateway scans and processes all incoming and outgoing email and makes sure that threats are not allowed in. Because attacks are increasingly sophisticated, standard security measures, such as blocking known bad file attachments, are no longer effective. | |
|--|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | | | |
|------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| <p>6.</p> | <p>a) Ans</p> | <p>Attempt any <u>TWO</u> of the following: Explain the process of transition from IPv4 to IPv6 for a network. Three Transitions from IPv4 to IPv6 strategies are:</p> <ol style="list-style-type: none"> 1. Dual Stack 2. Tunnelling 3. Header Translation <p>1. Dual Stack</p> <p>In this kind of strategy, a station has a dual stack of protocols run IPv4 and IPv6 simultaneously. To determine which version to use when sending a packet to a destination, the source host queries the DNS. If the DNS returns an IPv4 address, the source host sends an IPv4 packet. If the DNS returns an IPv6 address, the source host sends an IPv6 packet.</p> | <p>6M <i>2M for each transition</i></p> |
|------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|

2. Tunnelling

Tunnelling is a strategy used when two computers using IPv6 want to communicate with each other and the packet must pass through a region that uses IPv4.

- To pass through this region, the packet must have an IPv4 address. So the IPv6 packet is encapsulated in an IPv4 packet when it enters the region.
- To make it clear that the IPv4 packet is carrying an IPv6 packet as data.

Fig. Tunnelling

3. Header Translation

In this case, the header format must be totally changed through header translation. The header of the IPv6 packet is converted to an IPv4 header see figure.

(ISO/IEC - 27001 - 2005 Certified)

SUMMER – 2023 EXAMINATION MODEL ANSWER

Subject: Advanced Computer Network

Subject Code: 22520

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).

| Q. No. | Sub Q.N. | Answer | Marking Scheme | | |
|--------|-------------|----------------------------------------------------------------------------------------------|------------------------------------------------|---------------------------------------------------------------|--------------------------------------------------|
| 1. | (a) Ans. | Attempt any FIVE of the following: Differentiate between IPv4 and IPv6. (any two) | | 10 2M <i>Any two points 1M each</i> | |
| | | Sr. No. | IPv4 | | IPv6 |
| | | 1 | IPv4 addresses are 32 bits i.e. 4 bytes length | | IPv6 addresses are 128 bits i.e. 16 bytes length |
| | | 2 | Header length is 20 bytes | | Header length is 40 bytes |
| | | 3 | Checksum is available in header | | No Checksum in header |
| | | 4 | IPv4 allows 5 different classes of IP address | | IPv6 allows storing an unlimited of IP address |
| | | 5 | No packet flow identification | | Packet flow identification is available |
| | | 6 | Limited addresses | | Larger address space |

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | | | |
|--|---------------------|-------------------------------------------|-----------|
| | (b) Ans. | State the four advantages of IPv6. | 2M |
|--|---------------------|-------------------------------------------|-----------|

- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

| | <p>(b) Ans.</p> | <p>Explain ICMP protocol. Describe the header format of ICMP. The Internet Control Message Protocol (ICMP) supports the unreliable and connectionless Internet Protocol (IP).</p> <ul style="list-style-type: none"> ICMP messages are encapsulated in IP datagrams. There are two categories of ICMP messages: error-reporting and query messages. The error-reporting messages report problems that a router or a host (destination) may encounter when it processes an IP packet. The query messages, which occur in pairs, help a host or a network manager get specific information from a router or another host. □ The checksum for ICMP is calculated using both the header and the data fields of the ICMP message. There are several tools that can be used in the Internet for debugging. We can find if a host or router is alive and running. Two of these tools are ping and traceroute. <p>Header Format:</p>  <p>An ICMP message has an 8-byte header and a variable-size data section. Although the general format of the header is different for each message type, the first 4 bytes are common to all. As Figure shows,</p> <ul style="list-style-type: none"> The first field, ICMP type, defines the type of the message. The code field specifies the reason for the particular message type. The last common field is the checksum field for checking errors □ The rest of the header is specific for each message type. | <p>4M</p> <p><i>Explanation 2M</i></p> <p><i>Format 1M</i></p> <p><i>Description 1M</i></p> |

the characters to a universal character set called network virtual terminal (NVT) characters and delivers them to the local TCP/IP protocol stack.

- The commands or text, in NVT form, travel through the Internet and arrive at the TCP/IP stack at the remote machine.
- Here the characters are delivered to the operating system and passed to the TELNET server, which changes the characters to the corresponding characters understandable by the remote computer.
- However, the characters cannot be passed directly to the operating system because the remote operating system is not designed to receive characters from a TELNET server: It is designed to receive characters from a terminal driver.
- A piece of software called a pseudo terminal driver is added which pretends that the characters are coming from a terminal.
- The operating system then passes the characters to the appropriate application program.

| | <p>(b)</p> <p>Ans.</p> | <p>Describe modern computer use dynamic routing. Explain with example how distance vector routing is used to route the packet & why count-to-infinity problem arises and how does it get solved? (Note: Any other description of the concept shall be considered.)</p> <p>Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives routing updates, and dynamically decides which routes are best to go into the routing table. This intelligent and hands-off approach that makes dynamic routing so useful in modern era.</p> <p>Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors.</p> <p>Distance vector routing:</p> <ol style="list-style-type: none"> 1. Distance Vector Routing is one of the dynamic routing algorithm. 2. It is suitable for packet switched network. 3. In distance vector routing, each router maintains a routing table. 4. It contains one entry for each router in the subnet. 5. This entry has two parts: <ol style="list-style-type: none"> a. The first part shows the preferred outgoing line to be used to reach the destination. b. Second part gives an estimate of the time or distance to the destination. <p>In distance vector routing, a node tells its neighbor about its distance to every other node in the network.</p> <p>Count to infinity problem:</p> <ol style="list-style-type: none"> 1. One of the important issue in Distance Vector Routing is Count to Infinity Problem. 2. Count to infinity is just another name for a routing loop. 3. In distance vector routing, routing loops usually occur when an | <p>6M</p> <p><i>2M for Dynamic routing concept</i></p> <p><i>2M for Distance vector routing and</i></p> <p><i>1M for Count to infinity</i></p> |

SUMMER – 2023 EXAMINATION

MODEL ANSWER

Subject: Advanced Computer Network

Subject Code:

- C and A, so it corrects its table and changes infinity to 3 (1 for B to C, and 2 for C to A, as C said).
- Once again, routers exchange their tables.
 - When C receives B's routing table, it sees that B has changed the weight of its link to A from 1 to 3, so C updates its table and changes the weight of the link to A to 4 (1 for C to B, and 3 for B to A, as B said).
 - This process loops until all nodes find out that the weight of link to A is infinity.
 - This situation is shown in the table below
 - In this way, Distance Vector Algorithms have a slow convergence rate.
 - One way to solve this problem is for routers to send information only to the neighbors that are not exclusive links to the destination.

| | B | C | D |
|---------------------------------------------------|--------------|----------|----------|
| Sum of Weight to A after link cut | ∞ , A | 2, B | 3, C |
| Sum of Weight to A after 1 st updating | 3, C | 2, B | 3, C |

MODEL ANSWER

| | | |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| | <ul style="list-style-type: none"> <input type="checkbox"/> Email encryption involves encrypting, or disguising, the content of email messages to protect potentially sensitive information from being read by anyone other than intended recipients. Email encryption often includes authentication. Email allows attackers to use it as a way to cause problems in attempt to profit. Whether through spam campaigns, malware and phishing attacks, sophisticated targeted attacks, or business email compromise (BEC), attackers try to take advantage of the lack of security of email to carry out their actions. <input type="checkbox"/> Since most organizations rely on email to do business, attackers exploit email in an attempt to steal sensitive information. Because email is an open format, it can be viewed by anyone who can intercept it. It can be easily read and the contents of an email by intercepting it. <input type="checkbox"/> Email Security Policies can be established by viewing the contents of emails flowing through their email servers. It's important to understand what is in the entire email in order to act appropriately. After these baseline policies are put into effect, an organization can enact various security policies on those emails. These email security policies can be as simple as removing all executable content from emails to more in-depth actions, like sending suspicious content to a sandboxing tool for detailed analysis. <input type="checkbox"/> If security incidents are detected by these policies, the organization needs to have actionable intelligence about the scope of the attack. <input type="checkbox"/> Enforce email encryption policies to prevent sensitive email information from falling into the wrong hands. <input type="checkbox"/> An email gateway scans and processes all incoming and outgoing email and makes sure that threats are not allowed in. <input type="checkbox"/> Because attacks are increasingly sophisticated, standard security measures, such as blocking known bad file attachments, are no longer effective. | <p><i>Any 6 points 1M each</i></p> |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|

MODEL ANSWER

Subject: Advanced Computer Network (Elect)

Subject Code: 22520

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for anyequivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

SUMMER – 2023 EXAMINATION

MODEL ANSWER

Subject: Advanced Computer Network (Elect)

Subject Code: 22520

SUMMER – 2023 EXAMINATION MODEL ANSWER

1. When the site receives a data chunk, it stores it at the end of the buffer (queue) and subtracts the size of the chunk from winSize. The TSN number of the chunk is stored in the cumTSN variable.
2. When the process reads a chunk, it removes it from the queue and adds the size of the removed chunk to winSize (recycling).
3. When the receiver decides to send a SACK, it checks the value of lastAck; if it is less than cumTSN, it sends a SACK with a cumulative TSN number equal to the cumTSN. It also includes the value of winSize as the advertised window size.

Sender Site:

The sender has one buffer (queue) and three variables: curTSN, rwnd, and inTransit, as shown in the following figure. We assume each chunk is 100 bytes long.

The buffer holds the chunks produced by the process that either have been sent or are ready to be sent. The first variable, curTSN, refers to the next chunk to be sent. All chunks in the queue with a TSN less than this value have been sent, but not acknowledged; they are outstanding. The second variable, rwnd, holds the last value advertised by the receiver (in bytes). The third variable, inTransit, holds the number of bytes in transit, bytes sent but not yet acknowledged. The following is the procedure used by the sender.

1. A chunk pointed to by curTSN can be sent if the size of the data is less than or equal to the quantity $rwnd - inTransit$. After sending the chunk, the value of curTSN is incremented by 1 and now points to the next chunk to be sent. The value of inTransit is incremented by the size of the data in the transmitted chunk.

SUMMER – 2023 EXAMINATION MODEL ANSWER

| | | |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| | <p>into a DHCP server-enabled network, it will send a query to the DHCP server requesting all the necessary information. When the query reaches the DHCP server, it will grant the new computer a new IP address and a lease - a time frame for which the computer can use this IP address, as well as other configuration details. The whole process takes place immediately after the new computer boots, and to be successful, it has to be completed before initiating IP based communication with other hosts in the network.</p> <p>Dynamic allocation When the DHCP server is configured to use dynamic allocation, this means that it uses a lease policy. This way, when an assigned IP address from the available pool is no longer used, it will be transferred back to the pool, making it available for someone else to use. The advantage of this method is that the IP addresses are used to their maximum - as soon as they are no longer used by the client, they are instantly made available to others. The disadvantage of this method is that a client will always have a random IP address.</p> <p>Static allocation The static allocation method is very popular in modern ISP networks, which do not use dial-up methods. With the static allocation, the DHCP sever keeps a database with all clients' LAN MAC addresses and gives them an IP address only if their MAC address is in the database. This way, the clients can be sure that they will be getting the same IP address every time. A DHCP server can be set to work using a combination of the allocation methods. For example, in a public Wi-Fi network, all of the known hosts and permanent clients can use the static allocation, whereas for guests, the dynamic allocation is used. This way, known hosts can always use the same IP address and the IP address pool is equally available to everyone.</p> | <p><i>Dynamic allocation</i> <i>1M</i></p> |

MODEL ANSWER

Subject: Advanced Computer Network (Elect)

Subject Code: 22520

- **Assign a link local address:**

If the device passes the uniqueness test, the device assigns the link- local address to its IP interface. The link-local address can be used for communication on the local network but not over the Internet.

- **Contact the router:**

The node tries to contact a local router for more information about continuing the configuration. This contact is performed either by listening for router advertisement messages sent periodically by the routers or by sending a specific router solicitation message to ask a router for information about what to do next.

- **Provide direction to the node:**

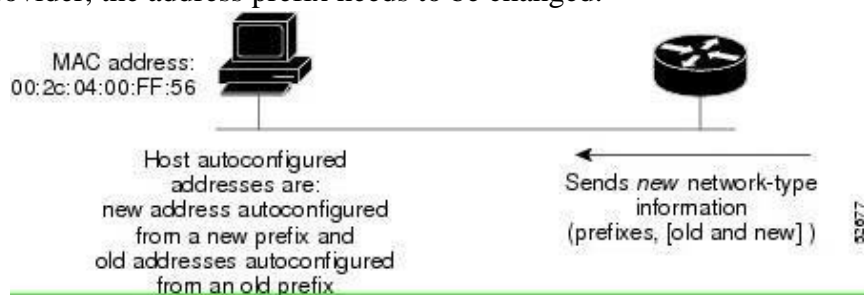

The router provides direction to the node about how to proceed with auto-configuration. Alternatively, the router tells the host how to determine the global Internet address.

- **Configure the global address:**

The host configures itself with its globally unique Internet address. This address is generally formed from a network prefix provided to the host by the router.

2. Renumbering:

To allow sites to change the service provider, renumbering of the address prefix (n) was built into IPv6 addressing. Each site is given a prefix by the service provider to which it is connected. If the site changes the provider, the address prefix needs to be changed.

| | | <p>2) Destination port address: - This is a 16-bit field that defines the port number of the application program in the host that is receiving the segment. This serves the same purpose as the destination port address in the UDP header.</p> <p>3) Sequence Number: - This 32-bit field defines the number assigned to the first byte of data contained in this segment. As we said before, TCP is a stream transport protocol. To ensure connectivity, each byte to be transmitted is numbered. The sequence number tells the destination which byte in this sequence comprises the first byte in the segment. During connection establishment, each party uses a random number generator to create an initial sequence number (ISN), which is usually different in each direction.</p> <p>4) Acknowledgment Number: - This 32-bit field defines the byte number that the receiver of the segment is expecting to receive from the other party. If the receiver of the segment has successfully received byte number x from the other party, it defines x + 1 as the acknowledgment number. Acknowledgment and data can be piggybacked together.</p> <p>5) Header length: - This 4-bit field indicates the number of 4-byte words in the TCP header. The length of the header can be between 20 and 60 bytes. Therefore, the value of this field can be between 5 (5 x 4 = 20) and 15 (15 x 4 = 60).</p> <p>6) Reserved:- This is a 6-bit field reserved for future use.</p> <p>7) Control Field:- This field defines 6 different control bits or flags. These are 6, 1 bit control bits that controls connection establishment, connection termination, connection abortion, flow control, mode of transfer etc.</p> | |

| | | <p>1) Multicast Distance Vector (DVMRP):</p> <p>Distance vector routing when extended to support multicast is called Distance Vector Multicast Routing Protocol (DVMRP). The DVMRP is Multicast routing protocol that takes the routing decision based upon the source address of the packet. This algorithm constructs the routing tree for a network. Whenever, a router receives a packet, it forwards it to some of its ports based on the source address of the packet. The rest of the routing tree is made by downstream routers. In this way, routing tree is created from destination to source.</p> <p>The DVMRP protocol must achieve the following tasks:</p> <ol style="list-style-type: none"> 1. It must prevent the formation of loops in the network. 2. It must prevent the formation of duplicate packets. 3. It must ensure that the path travelled by a packet is the shortest from its source to the router. 4. It should provide dynamic membership. <p>It is a following two-stage process:</p> <ol style="list-style-type: none"> 1. Create a broadcast mechanism that allows a packet to be forwarded to all the networks on the internet. 2. Refine this mechanism so that it prunes back networks that do not have hosts that belong to the multicast group. <p>Multicast distance vector routing uses source-based trees, but the router never actually makes a routing table. When a router receives a multicast packet, it forwards the packet as though it is consulting a routing table.</p> <p>We can say that the shortest path tree is evanescent. After its use (after a packet is forwarded) the table is destroyed. To accomplish this, the multicast distance vector algorithm uses a process based on following four decision-making strategies:</p> <p>1. Flooding:</p> <p>It is the first strategy that comes to mind. A router receives a packet and without even looking at the destination group address, sends it out from every interface except the one from which it was received.</p> | |

|--------------|

interface and be forwarded again.

Some flooding protocols keep a copy of the packet for a while and discard any duplicates to avoid loops. The next strategy, reverse path forwarding, corrects this defect.

2. Reverse Path Forwarding (RPF):

RPF is a modified flooding strategy. RPF eliminates the loop in the flooding processes.

In this strategy, the router only forwards those packets that have travelled the shortest path from source to destination.

To achieve this, the router pretends that it has a packet to send to the source from has arrived. In this way, the shortest path to the sender of the packet is computed.

If the same route is followed by the received packet, it is forwarded to the next router and it is discarded otherwise.

The reverse path forwarding ensures that the network receives a copy of the packet without formation of loops. A loop occurs when a packet that has left the router may come back again from another interface or the same interface and be forwarded again.

RPF does not guarantee that there would be no duplicate packets in the network i.e. the network may receive two or more copies. The reason for this is that the routing is based on the source address and not on the destination address.

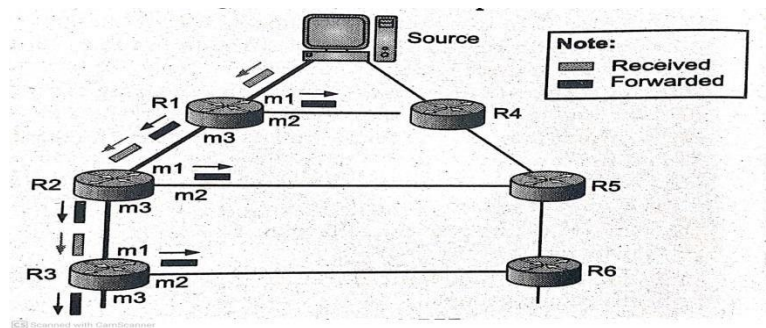

Fig. RPF

3. Reverse Path Broadcasting (RPB)

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | | | |
|--|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | | <p>RPF does not guarantee that each network receives only one copy a network receives two or more copies. The reason is that RPF is not based on the destination address forwarding is based on the source address. In order to solve the problem, RPB is used.</p> | |

SUMMER - 2023 EXAMINATION

MODEL ANSWER

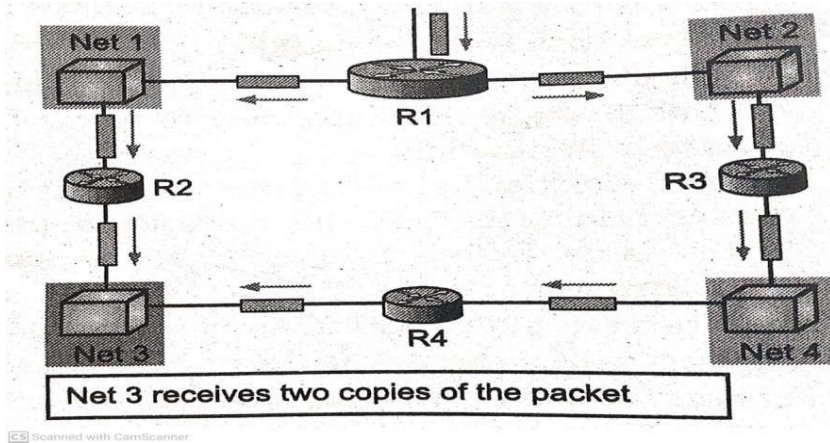

Fig. Problem with RPF

Consider the above Fig in which Net3 receives two copies of the packet even though each router just sends out one copy from each interface. There is duplication because a tree has not been made instead of a tree we have a graph. Net3 has two parents namely, routers R2 and R4.

In RPB method, one parent router is defined for each network. The network could accept the multicast packets from this parent router only. This router sends packets to those ports for which it is designated as parent.

Thus, RPB principle allows a router to broadcast the packet in the network. This creates duplicate packets on the network and reduces the network efficiency

To eliminate duplication, we must define only one parent router for each network. We must have this restriction: A network can receive a multicast packet from a particular source only through a designated parent router.

Now the policy is clear. For each source, the router sends the packet only out of those interfaces for which it is the designated parent. This policy is called Reverse Path Broadcasting (RPB).

4. Reverse Path Multicasting (RPM):

To overcome the problem of broadcasting in RPB, Reverse Path Multicasting is used. In RPM the desired multicast network tree is created by using two methods namely, Pruning and Grafting. A router can send a prune message to its upstream router whenever it finds that its network is not interested in a multicast packet. In this way a router prunes (cuts) its network from multicasting.

If a router receives prune message from all the downstream routers, it in turn, sends a prune Message to its upstream router.

To convert broadcasting to multicasting, the protocol uses following two procedures, pruning and grafting. **i) Pruning:**

The designated parent router of each network is responsible for holding the membership information. This is done through the IGMP protocol.

The process starts when a router connected to a network finds that there is no interest in a multicast packet. The router sends a prune message to the upstream router so that it can prune the corresponding interface.

That is, the upstream router can stop sending multicast messages for this group through that interface. Now if this router receives prune messages from all downstream routers, it, in turn, sends a prune message to its upstream router.

(ii) Grafting:

MODEL ANSWER

Following Fig. shows the idea of pruning and grafting.

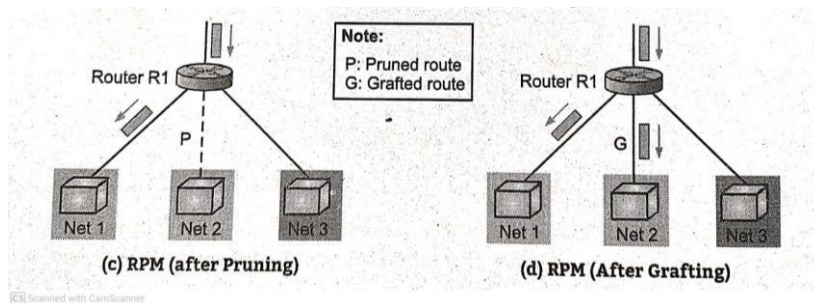

Fig.RPM Pruning and Grafting

2) Multicast Link State (MOSPF)

MOSPF protocol is an extension of the OSPF protocol that uses multicast link state routing to create source based trees.

MOSPF provides enhancements to OSPF Version 2 (OSPFV2) to support IP multicast routing.

The protocol requires a new link state update packet to associate the unicast address of a host with the group address only report directly connected hosts. This packet is called the group-membership LSA (Link State Advertisement).

MOSPF is a data driven protocol; the first time an MOSPF router sees a datagram with a given source and group address, the router constructs the Dijkstra shortest path tree.

MOSPF takes advantage of the link-state information maintained by OSPF.

Using the link-state and group membership information, MOSPF routers are able to calculate pruned source rooted shortest-path trees for multicast datagrams by using the Dijkstra's algorithm.

MOSPF also defines a mechanism for inter-AS multicast forwarding. The biggest disadvantage of MOSPF is that every router must maintain membership information of every group. Therefore, MOSPF also scales poorly if there are many multicast groups.

When compared to DVMRP, MOSPF causes no useless data traffic.

|--|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | | <p>3) Protocol Independent Multicast (PIM) PIM emerged as an algorithm to overcome the limitations of protocol such as the Distance Vector Multicast Routing Protocol (DVMRP),</p> | |
|--|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

SUMMER – 2023 EXAMINATION

MODEL ANSWER

Subject: Advanced Computer Network (Elect)

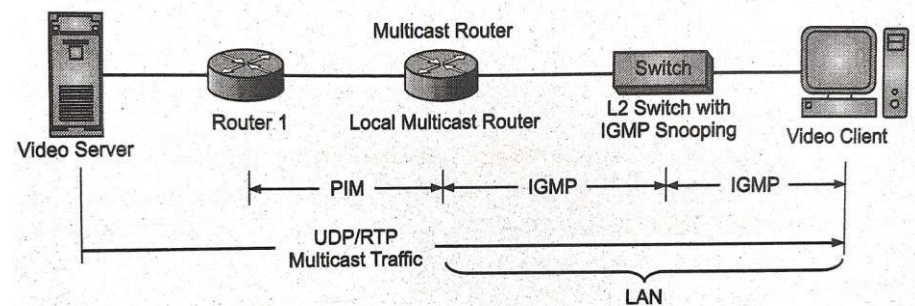

Subject Code: 22520

PIM was designed to avoid the dense-mode scaling issues of DVMRP and the potential performance issues of CBT (Core Base Tree) at the same time.

PIM is used for efficient routing to multicast groups that might span wide-area and inter domain internetworks. It is called “protocol independent” because it does not depend on a particular unicast routing protocol.

Protocol Independent Multicast (PIM) is a family of multicast routing protocols for Internet Protocol (IP) networks that provide one-to-many and many-to-many distribution of data over a LAN, WAN or the Internet.

PIM is not dependent on a specific unicast routing protocol; it can make use of any unicast routing protocol in use on the network. PIM does not build its own routing tables. PIM uses the unicast routing table for reverse path forwarding.

Protocol Independent Multicast (PIM) is the name given to two independent multicast routing protocols namely, Protocol Independent Multicast, Dense Mode (PIM-DM) and Protocol Independent Multicast, Sparse Mode (PIM-SM). Both protocols are unicast-protocol dependent, but the similarity ends here.

SUMMER – 2023 EXAMINATION MODEL ANSWER

22520

| | | |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | <p>PIM-DM: PIM Dense Mode (PIM-DM) is a multicast routing protocol designed with the opposite assumption to PIM-SM, namely that the receivers for any multicast group are distributed densely throughout the network. PIM-DM is used when there is a possibility that each router is involved in multicasting (dense mode). In this environment, the use of a protocol that broadcasts the packet is justified because almost all routers are involved in the process.</p> | |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

Subject: Advanced Computer Network (Elect)

Subject Code:

| | | |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | <p>PIM-DM is a source-based tree routing protocol that uses RPF and pruning/grafting strategies for multicasting. Its operation is like DVMRP; however, unlike DVMRP, it does not depend on a specific unicasting protocol.</p> <p>It assumes that the autonomous system is using a unicast protocol and each router has a table that can find the outgoing interface that has an optimal path to a destination. This unicast protocol can be a distance vector protocol (RIP) or link state protocol (OSPF).</p> <p>PIM-DM is used in a dense multicast environment, such as a LAN. PIM-DM uses RPF and pruning/grafting strategies to handle multicasting. However, it is independent from the underlying unicast protocol.</p> | |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | | |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| | <p>PIM-SM: PIM Sparse Mode (PIM-SM) is a multicast routing protocol designed on the assumption that recipients for any particular multicast group will be sparsely distributed throughout the network. PIM-SM is used when there is a slight possibility that each router is involved in multicasting (sparse mode). In this environment, the use of a protocol that broadcasts the packet is not justified; a protocol such as CBT (Core Base Tree) that uses a group-shared tree is more appropriate. PIM-SM is a group-shared tree routing protocol that has a Rendezvous Point (RP) as the source of the tree. Its operation is like CBT; however, it is simpler because it does not require acknowledgment from a join message. PIM-SM is used in a sparse multicast environment such as a WAN. PIM-SM is similar to CBT but uses a simpler procedure.</p> | |
| <p>c) Ans.</p> | <p>Describe the HTTP Responses Message Format. A Response message consists of a status line header line, a blank line and sometimes a body. | <p>d) Ans.</p> | <p>List different timers used in TCP.</p> <p>TCP uses several timers to ensure that excessive delays are not encountered during communications. Several of these timers are elegant, handling problems that are not immediately obvious at first analysis. Each of the timers used by TCP is examined in the following subsections, which reveal its role in ensuring data is properly sent from one connection to another. TCP implementations use at least four timers as shown in following Fig.</p> <div style="text-align: center;">  <pre> graph TD A[TCP Timers] --> B[Retransmission] A --> C[Persistence] A --> D[Keepalive] A --> E[Time-Wait] </pre> </div> <p>Fig.TCP Timers 1) Retransmission Timer:</p> <p>To retransmit lost segments, TCP uses Retransmission Time Out (RTO). When TCP sends a segment the timer starts and stops when the acknowledgment is received. If the timer expires timeout occurs and the segment is retransmitted. RTO (retransmission timeout is for 1 RTT) to calculate retransmission timeout we first need to calculate the RTT.</p> <p>Three Types of RTT:</p> <ol style="list-style-type: none"> 1. Measured RTT (RTT_m): The measured Round Trip Time (RTT) for a segment is the time required for the segment to reach the destination and be acknowledged, although the acknowledgment may include other segments. 2. Smoothed RTT (RTT_s): It is the weighted average of RTT_m. RTT_m is likely to change and its fluctuation is so high that a single measurement cannot be used to calculate RTO. <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="width: 10%; text-align: center;">(i)</td> <td style="width: 60%;">Initially</td> <td style="width: 30%;">No value</td> </tr> <tr> <td style="text-align: center;">(ii)</td> <td>After the first measurement</td> <td>$RTT_s = RTT_m$.</td> </tr> <tr> <td style="text-align: center;">(iii)</td> <td>After each measurement</td> <td>$RTT_s = (1 - 1) * RTT_s + t * RTT_m$.</td> </tr> </table> | (i) | Initially | No value | (ii) | After the first measurement | $RTT_s = RTT_m$. | (iii) | After each measurement | $RTT_s = (1 - 1) * RTT_s + t * RTT_m$. | <p>4M</p> <p><i>Diagram 1M</i></p> <p><i>List 1M</i></p> <p><i>Explanation 2M</i></p> <p><i>Any other relevant explanation shall be considered.</i></p> |
| (i) | Initially | No value | | | | | | | | | |
| (ii) | After the first measurement | $RTT_s = RTT_m$. | | | | | | | | | |
| (iii) | After each measurement | $RTT_s = (1 - 1) * RTT_s + t * RTT_m$. | | | | | | | | | |

3. Deviated RTT (RTTd): Most implementation do not use RTTS alone so RTT deviated is also calculated to find out RTO.

| | | |
|-------|-------------------------|-------------------------------------------|
| (i) | Initially | No value |
| (ii) | After first measurement | $RTTd = RTTm/2$ |
| (iii) | After each measurement | $RTTd = (1-k) * RTTd + k * (RTTm - RTTS)$ |

Retransmission Timeout:

RTO Calculation: The value of RTO is based on the smoothed round-trip time and its deviation. Most implementations use the following formula to calculate the RTO:

Initial value → Original (given in question).

After any measurement → $RTO = RTTs + 4 * RTTd$

2) Persistent Timer:

To deal with a zero-window-size deadlock situation, TCP uses a persistence timer. When the sending TCP receives an acknowledgment with a window size of zero, it starts a persistence timer.

When the persistence timer goes off, the sending TCP sends a special segment called a probe. This segment contains only 1 byte of new data. It has a sequence number, but its sequence number is never acknowledged; it is even ignored in calculating the sequence number for the rest of the data. The probe causes the receiving TCP to resend the acknowledgment which was lost.

3) Keepalive Timer:

A keepalive timer is used to prevent a long idle connection between two TCPs. If a client opens a TCP connection to a server transfers some data and becomes silent the client will crash.

In this case, the connection remains open forever. So a keepalive timer is used. Each time the server hears from a client, it resets this timer. The time-out is usually 2 hours. . If the server does not hear from the client after 2 hours, it sends a probe segment. If there is no response after 10 probes, each of which is 75 s apart, it assumes that the client is down and terminates the connection.

| 5. | a) Ans. | <p>Attempt any <u>TWO</u> of the following: Describe the BGP3 in detail.</p> <ul style="list-style-type: none"> • To denote any protocol used to pass routing information between two autonomous systems, Computer scientists use the term Exterior Gateway Protocol (EGP). Currently a single exterior protocol is used in most TCPJIP internets. Known as the Border Gateway Protocol (BGP), it has evolved through four (quite different) versions one of the versions is BGP3. • Two systems form a transport protocol connection between one another. They exchange messages to open and confirm the connection parameters. The initial data flow is the entire BGP routing table. • Incremental updates are sent as the routing tables change. BGP does not require periodic refresh of the entire BGP routing table. Therefore, a BGP speaker must retain the current version of the entire BGP routing tables of all of its peers for the duration of the connection. • Keepalive messages are sent periodically to ensure the liveness of the connection. • Notification messages are sent in response to errors or special conditions. If a connection encounters an error condition, a notification message is sent and the connection is closed. • Connections between BGP speakers of different ASs are referred to as "external" links. BGP connections between BGP speakers within the same AS are referred to as "internal" links. • Messages are sent over a reliable transport protocol connection. A message is processed only after it is entirely received. The maximum message size is 4096 octets. All implementations are required to support this maximum message size. | <p>12 6M</p> <p><i>Explanation 3M for Message Format diagram and explanation with message types 3M</i></p> |

|--------------|

2. Tunnelling

Tunnelling is a strategy used when two computers using IPv6 want to communicate with each other and the packet must pass through a region that uses IPv4.

- To pass through this region, the packet must have an IPv4 address. So the IPv6 packet is encapsulated in an IPv4 packet when it enters the region.
- To make it clear that the IPv4 packet is carrying an IPv6 packet as data.

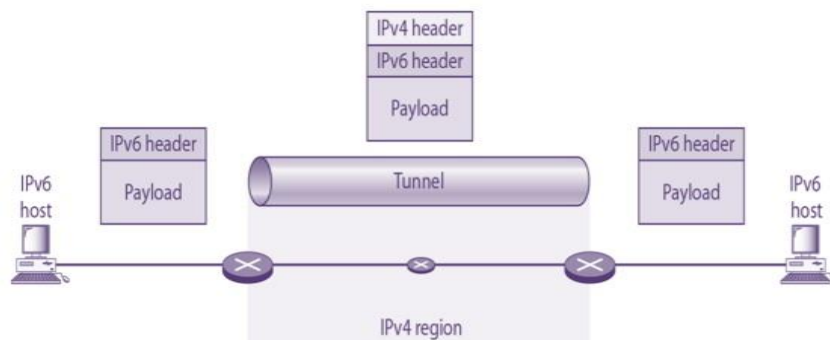

Fig. Tunnelling

3. Header Translation

In this case, the header format must be totally changed through header translation. The header of the IPv6 packet is converted to an IPv4 header see figure.

SUMMER – 2023 EXAMINATION MODEL ANSWER

about all its neighbors to the entire Internet in a process called flooding, as discussed earlier. For this, it sends a special packet called Link State Packet (LSP) to all other routers via its neighbors.

For example, a sample portion of the LSP (shown only for router A about its neighbors) could take the form as shown below

LSP for r

| Advertiser | Network | Cost | Neighbor |
|------------|---------|------|----------|
| A | 1 | 1 | B |
| A | 6 | 3 | F |
| A | 5 | 2 | E |

outer A (Cost is Assumed in example)

For example, the first row says that between router A (the first column) and router B (the fourth column), there is network 1 (the second column), and that the cost of going from router A to router B is 1 (the fourth column).

Every router receives every LSP packet, and uses it to create a local database called link state database. Thus, a link state database is a collection of all LSPs. Every router stores such a database on its disk,

SUMMER – 2023 EXAMINATION

MODEL ANSWER

and uses it for routing packets. A sample link state database for our example Internet is shown below

| Advertiser | Network | Cost | Neighbor |
|------------|---------|------|----------|
| A | 1 | 1 | B |
| A | 6 | 3 | F |
| A | 5 | 2 | E |
| B | 1 | 4 | A |
| B | 2 | 2 | C |
| C | 2 | 5 | B |
| C | 3 | 2 | D |
| D | 3 | 5 | C |

SUMMER – 2023 EXAMINATION

MODEL ANSWER

| | | | |
|--|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| | <p>c)</p> <p>Ans.</p> | <p>Describe e-mail security over non-secure channel. <i>(Note: Any other description of the concept shall be considered.)</i></p> <ul style="list-style-type: none"> • Email security describes different techniques for keeping sensitive information in email communication and accounts secure against unauthorized access, loss or compromise. • Email is often used to spread malware, spam and phishing attacks. Attackers use deceptive messages to entice recipients to part with sensitive information, open attachments or click on hyperlinks that install malware on the victim’s device. • Email encryption involves encrypting, or disguising, the content of email messages to protect potentially sensitive information from being read by anyone other than intended recipients. Email encryption often includes authentication. • Email allows attackers to use it as a way to cause problems in attempt to profit. Whether through spam campaigns, malware and phishing attacks, sophisticated targeted attacks, or business email compromise (BEC), attackers try to take advantage of the lack of security of email to carry out their actions. • Since most organizations rely on email to do business, attackers exploit email in an attempt to steal sensitive information. • Because email is an open format, it can be viewed by anyone who can intercept it. It can be easily read and the contents of an email by intercepting it. • Email Security Policies can be established by viewing the contents of emails flowing through their email servers. It’s important to | <p>6M</p> <p><i>Any six points 1M each</i></p> |

|--|--|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| | | <p>understand what is in the entire email in order to act appropriately. After these baseline policies are put into effect, an organization can enact various security policies on those emails.</p> <ul style="list-style-type: none"> • These email security policies can be as simple as removing all executable content from emails to more in-depth actions, like sending suspicious content to a sandboxing tool for detailed analysis. • If security incidents are detected by these policies, the organization needs to have actionable intelligence about the scope of the attack. • Enforce email encryption policies to prevent sensitive email information from falling into the wrong hands. • An email gateway scans and processes all incoming and outgoing email and makes sure that threats are not allowed in. Because attacks are increasingly sophisticated, standard security measures, such as blocking known bad file attachments, are no longer effective. | |
